Package ‘igraph’

February 20, 2015

Version 0.7.1
Date 2014-04-22
Title Network analysis and visualization
Author See AUTHORS file.
Maintainer Gabor Csardi <csardi.gabor@gmail.com>
Description Routines for simple graphs and network analysis. igraph can handle large graphs very well and provides functions for generating random and regular graphs, graph visualization, centrality indices and much more.
Depends methods
Imports Matrix
Suggests igraphdata, stats4, rgl, tcltk, graph, ape

igraph-package

Description

igraph is a library and R package for network analysis.

Introduction

The main goals of the igraph library is to provide a set of data types and functions for 1) pain-free implementation of graph algorithms, 2) fast handling of large graphs, with millions of vertices and edges, 3) allowing rapid prototyping via high level languages like R.
Igraph graphs

Igraph graphs have a class ‘igraph’. They are printed to the screen in a special format, here is an example, a ring graph created using `graph.ring`:

```
IGRAPH U--- 10 10 -- Ring graph
  + attr: name (g/c), mutual (g/x), circular (g/x)
```

The ‘IGRAPH’ denotes that this is an igraph graph. Then come four bits that denote the kind of the graph: the first is ‘U’ for undirected and ‘D’ for directed graphs. The second is ‘N’ for named graph (i.e. if the graph has the ‘name’ vertex attribute set). The third is ‘W’ for weighted graphs (i.e. if the ‘weight’ edge attribute is set). The fourth is ‘B’ for bipartite graphs (i.e. if the ‘type’ vertex attribute is set).

Then comes two numbers, the number of vertices and the number of edges in the graph, and after a double dash, the name of the graph (the ‘name’ graph attribute) is printed if present. The second line is optional and it contains all the attributes of the graph. This graph has a ‘name’ graph attribute, of type character, and two other graph attributes called ‘mutual’ and ‘circular’, of a complex type. A complex type is simply anything that is not numeric or character. See the documentation of `print.igraph` for details.

If you want to see the edges of the graph as well, then use the `str.igraph` function, it is of course enough to type `str` instead of `str.igraph`:

```
> str(g)
IGRAPH U--- 10 10 -- Ring graph
  + attr: name (g/c), mutual (g/x), circular (g/x)
  + edges:
[1] 1-- 2 2-- 3 3-- 4 4-- 5 5-- 6 6-- 7 7-- 8 8-- 9 9--10 1--10
```

Creating graphs

There are many functions in igraph for creating graphs, both deterministic and stochastic; stochastic graph constructors are called ‘games’.

To create small graphs with a given structure probably the `graph.formula` function is easiest. It uses R’s formula interface, its manual page contains many examples. Another option is `graph`, which takes numeric vertex ids directly. `graph.atlas` creates graph from the Graph Atlas, `graph.famous` can create some special graphs.

To create graphs from field data, `graph.edgelist`, `graph.data.frame` and `graph.adjacency` are probably the best choices.

The igraph package includes some classic random graphs like the Erdos-Renyi GNP and GNM graphs (`erdos.renyi.game`) and some recent popular models, like preferential attachment (`barabasi.game`) and the small-world model (`watts.strogatz.game`).

Vertex and edge IDs

Vertices and edges have numerical vertex ids in igraph. Vertex ids are always consecutive and they start with one. I.e. for a graph with n vertices the vertex ids are between 1 and n. If some operation changes the number of vertices in the graphs, e.g. a subgraph is created via `induced.subgraph`, then the vertices are renumbered to satisfy this criteria.
The same is true for the edges as well, edge ids are always between one and $m$, the total number of edges in the graph.

It is often desirable to follow vertices along a number of graph operations, and vertex ids don’t allow this because of the renumbering. The solution is to assign attributes to the vertices. These are kept by all operations, if possible. See more about attributes in the next section.

**Attributes**

In igraph it is possible to assign attributes to the vertices or edges of a graph, or to the graph itself. igraph provides flexible constructs for selecting a set of vertices or edges based on their attribute values, see `get.vertex.attribute` and `iterators` for details.

Some vertex/edge/graph attributes are treated specially. One of them is the ‘name’ attribute. This is used for printing the graph instead of the numerical ids, if it exists. Vertex names can also be used to specify a vector or set of vertices, in all igraph functions. E.g. `degree` has a `v` argument that gives the vertices for which the degree is calculated. This argument can be given as a character vector of vertex names.

Edges can also have a ‘name’ attribute, and this is treated specially as well. Just like for vertices, edges can also be selected based on their names, e.g. in the `delete.edges` and other functions.

We note here, that vertex names can also be used to select edges. The form ‘from|to’, where ‘from’ and ‘to’ are vertex names, select a single, possibly directed, edge going from ‘from’ to ‘to’. The two forms can also be mixed in the same edge selector.

Other attributes define visualization parameters, see `igraph.plotting` for details.

Attribute values can be set to any R object, but note that storing the graph in some file formats might result the loss of complex attribute values. All attribute values are preserved if you use `save` and `load` to store/retrieve your graphs.

**Visualization**

igraph provides three different ways for visualization. The first is the `plot.igraph` function. (Actually you don’t need to write `plot.igraph`, `plot` is enough. This function uses regular R graphics and can be used with any R device.

The second function is `tkplot`, which uses a Tk GUI for basic interactive graph manipulation. (Tk is quite resource hungry, so don’t try this for very large graphs.)

The third way requires the `rgl` package and uses OpenGL. See the `rglplot` function for the details. Make sure you read `igraph.plotting` before you start plotting your graphs.

**File formats**

igraph can handle various graph file formats, usually both for reading and writing. We suggest that you use the GraphML file format for your graphs, except if the graphs are too big. For big graphs a simpler format is recommended. See `read.graph` and `write.graph` for details.

**Further information**

The igraph homepage is at [http://igraph.org](http://igraph.org). See especially the documentation section. Join the igraph-help mailing list if you have questions or comments.
adjacent.triangles  
Count adjacent triangles

Description
Count how many triangles a vertex is part of, in a graph.

Usage
adjacent.triangles (graph, vids = V(graph))

Arguments
- graph: The input graph. It might be directed, but edge directions are ignored.
- vids: The vertices to query, all of them by default. This might be a vector of numeric ids, or a character vector of symbolic vertex names for named graphs.

Details
Count how many triangles a vertex is part of.

Value
A numeric vector, the number of triangles for all vertices queried.

Author(s)
Gabor Csardi <csardi.gabor@gmail.com>

See Also
transitivity

Examples
```r
## A small graph
kite <- graph.famous("Krackhardt_Kite")
atri <- adjacent.triangles(kite)
plot(kite, vertex.label=atri)

## Should match, local transitivity is the
## number of adjacent triangles divided by the number
## of adjacency triples
transitivity(kite, type="local")
adjacent.triangles(kite) / (degree(kite) * (degree(kite)-1)/2)
```
aging.prefatt.game

Generate an evolving random graph with preferential attachment and aging

Description

This function creates a random graph by simulating its evolution. Each time a new vertex is added it creates a number of links to old vertices and the probability that an old vertex is cited depends on its in-degree (preferential attachment) and age.

Usage

aging.prefatt.game(n, pa.exp, aging.exp, m = NULL, aging.bin = 300,
out.dist = NULL, out.seq = NULL, out.pref = FALSE,
directed = TRUE, zero.deg.appeal = 1, zero.age.appeal = 0,
deg.coef = 1, age.coef = 1, time.window = NULL)

Arguments

n
The number of vertices in the graph.

pa.exp
The preferential attachment exponent, see the details below.

aging.exp
The exponent of the aging, usually a non-positive number, see details below.

m
The number of edges each new vertex creates (except the very first vertex). This argument is used only if both the out.dist and out.seq arguments are NULL.

aging.bin
The number of bins to use for measuring the age of vertices, see details below.

out.dist
The discrete distribution to generate the number of edges to add in each time step if out.seq is NULL. See details below.

out.seq
The number of edges to add in each time step, a vector containing as many elements as the number of vertices. See details below.

out.pref
Logical constant, whether to include edges not initiated by the vertex as a basis of preferential attachment. See details below.

directed
Logical constant, whether to generate a directed graph. See details below.

zero.deg.appeal
The degree-dependent part of the ‘attractiveness’ of the vertices with no adjacent edges. See also details below.

zero.age.appeal
The age-dependent part of the ‘attractiveness’ of the vertices with age zero. It is usually zero, see details below.

deg.coef
The coefficient of the degree-dependent ‘attractiveness’. See details below.

age.coef
The coefficient of the age-dependent part of the ‘attractiveness’. See details below.

time.window
Integer constant, if NULL only adjacent added in the last time.windows time steps are counted as a basis of the preferential attachment. See also details below.
Details

This is a discrete time step model of a growing graph. We start with a network containing a single vertex (and no edges) in the first time step. Then in each time step (starting with the second) a new vertex is added and it initiates a number of edges to the old vertices in the network. The probability that an old vertex is connected to is proportional to

\[ P[i] \sim (c \cdot k_i^\alpha + a)(d \cdot l_i^{\beta} + b) \]

Here \( k_i \) is the in-degree of vertex \( i \) in the current time step and \( l_i \) is the age of vertex \( i \). The age is simply defined as the number of time steps passed since the vertex is added, with the extension that vertex age is divided to be in agingNbin bins.

c, \( \alpha \), a, d, \( \beta \) and b are parameters and they can be set via the following arguments: pa.exp (\( \alpha \), mandatory argument), aging.exp (\( \beta \), mandatory argument), zero.deg.appeal (a, optional, the default value is 1), zero.age.appeal (b, optional, the default is 0), deg.coef (c, optional, the default is 1), and age.coef (d, optional, the default is 1).

The number of edges initiated in each time step is governed by the m, out.seq and out.pref parameters. If out.seq is given then it is interpreted as a vector giving the number of edges to be added in each time step. It should be of length \( n \) (the number of vertices), and its first element will be ignored. If out.seq is not given (or NULL) and out.dist is given then it will be used as a discrete probability distribution to generate the number of edges. Its first element gives the probability that zero edges are added at a time step, the second element is the probability that one edge is added, etc. (out.seq should contain non-negative numbers, but if they don’t sum up to 1, they will be normalized to sum up to 1. This behavior is similar to the prob argument of the sample command.)

By default a directed graph is generated, but if directed is set to FALSE then an undirected is created. Even if an undirected graph is generated \( k_i \) denotes only the adjacent edges not initiated by the vertex itself except if out.pref is set to TRUE.

If the time.window argument is given (and not NULL) then \( k_i \) means only the adjacent edges added in the previous time.window time steps.

This function might generate graphs with multiple edges.

Value

A new graph.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

barabasi.game, erdos.renyi.game

Examples

# The maximum degree for graph with different aging exponents
g1 <- aging.prefatt.game(10000, pa.exp=1, aging.exp=0, aging.bin=1000)
g2 <- aging.prefatt.game(10000, pa.exp=1, aging.exp=-1, aging.bin=1000)
alpha.centrality

Find Bonacich alpha centrality scores of network positions

alpha.centrality calculates the alpha centrality of some (or all) vertices in a graph.

Usage

alpha.centrality(graph, nodes=V(graph), alpha=1, loops=FALSE, exo=1, weights=NULL, tol=1e-7, sparse=TRUE)

Arguments

- graph: The input graph, can be directed or undirected
- nodes: Vertex sequence, the vertices for which the alpha centrality values are returned. (For technical reasons they will be calculated for all vertices, anyway.)
- alpha: Parameter specifying the relative importance of endogenous versus exogenous factors in the determination of centrality. See details below.
- loops: Whether to eliminate loop edges from the graph before the calculation.
- exo: The exogenous factors, in most cases this is either a constant – the same factor for every node, or a vector giving the factor for every vertex. Note that too long vectors will be truncated and too short vectors will be replicated to match the number of vertices.
- weights: A character scalar that gives the name of the edge attribute to use in the adjacency matrix. If it is NULL, then the ‘weight’ edge attribute of the graph is used, if there is one. Otherwise, or if it is NA, then the calculation uses the standard adjacency matrix.
- tol: Tolerance for near-singularities during matrix inversion, see solve.
- sparse: Logical scalar, whether to use sparse matrices for the calculation. The ‘Matrix’ package is required for sparse matrix support

Details

The alpha centrality measure can be considered as a generalization of eigenvector centrality to directed graphs. It was proposed by Bonacich in 2001 (see reference below).

The alpha centrality of the vertices in a graph is defined as the solution of the following matrix equation:

\[ x = \alpha A^T x + e, \]

where \( A \) is the (not necessarily symmetric) adjacency matrix of the graph, \( e \) is the vector of exogenous sources of status of the vertices and \( \alpha \) is the relative importance of the endogenous versus exogenous factors.
Value

A numeric vector containing the centrality scores for the selected vertices.

Warning

Singular adjacency matrices cause problems for this algorithm, the routine may fail in certain cases.

```

Description

Interface to the ARPACK library for calculating eigenvectors of sparse matrices

Usage

```r
arpack(func, extra = NULL, sym = FALSE, options = igraph.arpack.default,
env = parent.frame(), complex=!sym)
arpack.unpack.complex(vectors, values, nev)
```
Arguments

func
The function to perform the matrix-vector multiplication. ARPACK requires to perform these by the user. The function gets the vector $x$ as the first argument, and it should return $Ax$, where $A$ is the “input matrix”. (The input matrix is never given explicitly.) The second argument is extra.

eextra
Extra argument to supply to func.

sym
Logical scalar, whether the input matrix is symmetric. Always supply TRUE here if it is, since it can speed up the computation.

options
Options to ARPACK, a named list to overwrite some of the default option values. See details below.

eenv
The environment in which func will be evaluated.

complex
Whether to convert the eigenvectors returned by ARPACK into R complex vectors. By default this is not done for symmetric problems (these only have real eigenvectors/values), but only non-symmetric ones. If you have a non-symmetric problem, but you’re sure that the results will be real, then supply FALSE here. The conversion is done by calling arpack.unpack.complex.

evectors
Eigenvectors, as returned by ARPACK.

evalues
Eigenvalues, as returned by ARPACK

enev
The number of eigenvectors/values to extract. This can be less than or equal to the number of eigenvalues requested in the original ARPACK call.

Details

ARPACK is a library for solving large scale eigenvalue problems. The package is designed to compute a few eigenvalues and corresponding eigenvectors of a general $n$ by $n$ matrix $A$. It is most appropriate for large sparse or structured matrices $A$ where structured means that a matrix-vector product $w \leftarrow Av$ requires order $n$ rather than the usual order $n^2$ floating point operations. Please see http://www.caam.rice.edu/software/ARPACK/ for details.

This function is an interface to ARPACK. igraph does not contain all ARPACK routines, only the ones dealing with symmetric and non-symmetric eigenvalue problems using double precision real numbers.

The eigenvalue calculation in ARPACK (in the simplest case) involves the calculation of the $Av$ product where $A$ is the matrix we work with and $v$ is an arbitrary vector. The function supplied in the fun argument is expected to perform this product. If the product can be done efficiently, e.g. if the matrix is sparse, then arpack is usually able to calculate the eigenvalues very quickly.

The options argument specifies what kind of calculation to perform. It is a list with the following members, they correspond directly to ARPACK parameters. On input it has the following fields:

- **bmat** Character constant, possible values: ‘I’, standard eigenvalue problem, $Ax = \lambda x$; and ‘G’, generalized eigenvalue problem, $Ax = \lambda Bx$. Currently only ‘I’ is supported.

- **n** Numeric scalar. The dimension of the eigenproblem. You only need to set this if you call arpack directly. (I.e., not needed for evcent, page.rank, etc.)

- **which** Specify which eigenvalues/vectors to compute, character constant with exactly two characters.

    Possible values for symmetric input matrices:
'LA' Compute nev largest (algebraic) eigenvalues.
'SA' Compute nev smallest (algebraic) eigenvalues.
'LM' Compute nev largest (in magnitude) eigenvalues.
'SM' Compute nev smallest (in magnitude) eigenvalues.
'BE' Compute nev eigenvalues, half from each end of the spectrum. When nev is odd, compute one more from the high end than from the low end.

Possible values for non-symmetric input matrices:
'LM' Compute nev eigenvalues of largest magnitude.
'SM' Compute nev eigenvalues of smallest magnitude.
'LR' Compute nev eigenvalues of largest real part.
'SR' Compute nev eigenvalues of smallest real part.
'LI' Compute nev eigenvalues of largest imaginary part.
'SI' Compute nev eigenvalues of smallest imaginary part.

This parameter is sometimes overwritten by the various functions, e.g. page.rank always sets 'LM'.

nev Numeric scalar. The number of eigenvalues to be computed.
tol Numeric scalar. Stopping criterion: the relative accuracy of the Ritz value is considered acceptable if its error is less than tol times its estimated value. If this is set to zero then machine precision is used.
ncv Number of Lanczos vectors to be generated.
ldv Numeric scalar. It should be set to zero in the current implementation.
ishift Either zero or one. If zero then the shifts are provided by the user via reverse communication. If one then exact shifts with respect to the reduced tridiagonal matrix $T$. Please always set this to one.
maxiter Maximum number of Arnoldi update iterations allowed.

nb Blocksize to be used in the recurrence. Please always leave this on the default value, one.

mode The type of the eigenproblem to be solved. Possible values if the input matrix is symmetric:
1 $Ax = \lambda x$, $A$ is symmetric.
2 $Ax = \lambda M x$, $A$ is symmetric, $M$ is symmetric positive definite.
3 $K x = \lambda M x$, $K$ is symmetric, $M$ is symmetric positive semi-definite.
4 $K x = \lambda KG x$, $K$ is symmetric positive semi-definite, $KG$ is symmetric indefinite.
5 $Ax = \lambda M x$, $A$ is symmetric, $M$ is symmetric positive semi-definite. (Cayley transformed mode.)

Please note that only mode==1 was tested and other values might not work properly.

Possible values if the input matrix is not symmetric:
1 $Ax = \lambda x$.
2 $Ax = \lambda M x$, $M$ is symmetric positive definite.
3 $Ax = \lambda M x$, $M$ is symmetric semi-definite.
4 $Ax = \lambda M x$, $M$ is symmetric semi-definite.

Please note that only mode==1 was tested and other values might not work properly.

start Not used currently. Later it be used to set a starting vector.
sigma Not used currently.
sigmai Not use currently.

On output the following additional fields are added:

info Error flag of ARPACK. Possible values:
  0 Normal exit.
  1 Maximum number of iterations taken.
  3 No shifts could be applied during a cycle of the Implicitly restarted Arnoldi iteration.
     One possibility is to increase the size of ncv relative to nev.

ARPACK can return more error conditions than these, but they are converted to regular
igraph errors.

iter Number of Arnoldi iterations taken.

nconv Number of “converged” Ritz values. This represents the number of Ritz values that
satisfy the convergence criterion.

numop Total number of matrix-vector multiplications.

numopb Not used currently.

numreo Total number of steps of re-orthogonalization.

Please see the ARPACK documentation for additional details.

arpacK::unpack_complex is a (semi-)internal function that converts the output of the non-symmetric
ARPACK solver to a more readable format. It is called internally by arpack.

Value

A named list with the following members:

values Numeric vector, the desired eigenvalues.

vectors Numeric matrix, the desired eigenvectors as columns. If complex=TRUE (the
default for non-symmetric problems), then the matrix is complex.

options A named list with the supplied options and some information about the per-
formed calculation, including an ARPACK exit code. See the details above.

}

articulation.points    Articulation points of a graph

Description

Articulation points or cut vertices are vertices whose removal increases the number of connected components in a graph.

Usage

articulation.points(graph)
Arguments

graph The input graph. It is treated as an undirected graph, even if it is directed.

Details

Articuation points or cut vertices are vertices whose removal increases the number of connected components in a graph. If the original graph was connected, then the removal of a single articulation point makes it undirected. If a graph contains no articulation points, then its vertex connectivity is at least two.

Value

A numeric vector giving the vertex ids of the articulation points of the input graph.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

See Also

biconnected.components, clusters.is.connected, vertex.connectivity

Examples

g <- graph.disjoint.union( graph.full(5), graph.full(5) )
clu <- clusters(g)$membership
g <- add.edges(g, c(match(1, clu), match(2, clu)) )
articulation.points(g)

as.directed Convert between directed and undirected graphs

Description

as.directed converts an undirected graph to directed, as.undirected does the opposite, it converts a directed graph to undirected.

Usage

as.directed(graph, mode = c("mutual", "arbitrary"))
as.undirected(graph, mode = c("collapse", "each", "mutual"),
    edge.attr.comb = getGraphOpt("edge.attr.comb"))
Arguments

- graph: The graph to convert.
- mode: Character constant, defines the conversion algorithm. For `as.directed` it can be mutual or arbitrary. For `as.undirected` it can be each, collapse or mutual. See details below.
- edge.attr.comb: Specifies what to do with edge attributes, if mode="collapse" or mode="mutual". In these cases many edges might be mapped to a single one in the new graph, and their attributes are combined. Please see `attribute.combination` for details on this.

Details

Conversion algorithms for `as.directed`:

- arbitrary: The number of edges in the graph stays the same, an arbitrarily directed edge is created for each undirected edge.
- mutual: Two directed edges are created for each undirected edge, one in each direction.

Conversion algorithms for `as.undirected`:

- each: The number of edges remains constant, an undirected edge is created for each directed one, this version might create graphs with multiple edges.
- collapse: One undirected edge will be created for each pair of vertices which are connected with at least one directed edge, no multiple edges will be created.
- mutual: One undirected edge will be created for each pair of mutual edges. Non-mutual edges are ignored. This mode might create multiple edges if there are more than one mutual edge pairs between the same pair of vertices.

Value

A new graph object.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

See Also

`simplify` for removing multiple and/or loop edges from a graph.

Examples

```r
g <- graph.ring(10)
as.directed(g, "mutual")
g2 <- graph.star(10)
as.undirected(g)

# Combining edge attributes
g3 <- graph.ring(10, directed=TRUE, mutual=TRUE)
```
as.igraph

Conversion to igraph

Description

These functions convert various objects to igraph graphs.

Usage

## S3 method for class 'igraphHRG'

as.igraph(x, ...)

Arguments

- x: The object to convert.
- ...: Additional arguments. None currently.

Details

You can use as.igraph to convert various objects to igraph graphs. Right now the following objects are supported:

- codeigraphHRG These objects are created by the hrg.fit and hrg.consensus functions.

Value

All these functions return an igraph graph.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>.
**Assortativity**

**Examples**

```r
g <- graph.full(5) + graph.full(5)
hrg <- hrg.fit(g)
as.igraph(hrg)
```

<table>
<thead>
<tr>
<th>assortativity</th>
<th>Assortativity coefficient</th>
</tr>
</thead>
</table>

**Description**

The assortativity coefficient is positive if similar vertices (based on some external property) tend to connect to each, and negative otherwise.

**Usage**

- `assortativity(graph, types1, types2 = NULL, directed = TRUE)`
- `assortativity.nominal(graph, types, directed = TRUE)`
- `assortativity.degree(graph, directed = TRUE)`

**Arguments**

- `graph` The input graph, it can be directed or undirected.
- `types` Vector giving the vertex types. They are assumed to be integer numbers, starting with one. Non-integer values are converted to integers with `as.integer`.
- `types1` The vertex values, these can be arbitrary numeric values.
- `types2` A second value vector to be using for the incoming edges when calculating assortativity for a directed graph. Supply NULL here if you want to use the same values for outgoing and incoming edges. This argument is ignored (with a warning) if it is not NULL and undirected assortativity coefficient is being calculated.
- `directed` Logical scalar, whether to consider edge directions for directed graphs. This argument is ignored for undirected graphs. Supply `TRUE` here to do the natural thing, i.e. use directed version of the measure for directed graphs and the undirected version for undirected graphs.

**Details**

The assortativity coefficient measures the level of homophily of the graph, based on some vertex labeling or values assigned to vertices. If the coefficient is high, that means that connected vertices tend to have the same labels or similar assigned values.

M.E.J. Newman defined two kinds of assortativity coefficients, the first one is for categorical labels of vertices. `assortativity.nominal` calculates this measure. It is defined as

$$ r = \frac{\sum_i e_{ii} - \sum_i a_i b_i}{1 - \sum_i a_i b_i} $$

where $e_{ij}$ is the fraction of edges connecting vertices of type $i$ and $j$, $a_i = \sum_j e_{ij}$ and $b_j = \sum_i e_{ij}$. 

- $e_{ij}$ is the fraction of edges connecting vertices of type $i$ and $j$.
- $a_i$ is the sum of the fractions of edges connecting vertices of type $i$.
- $b_j$ is the sum of the fractions of edges connecting vertices of type $j$. 

```r
g <- graph.full(5) + graph.full(5)
hrg <- hrg.fit(g)
as.igraph(hrg)
```
The second assortativity variant is based on values assigned to the vertices. assortativity calculates this measure. It is defined as

$$r = \frac{1}{\sigma^2} \sum_{jk} jk(e_{jk} - q_j q_k)$$

for undirected graphs ($q_i = \sum_j e_{ij}$) and as

$$r = \frac{1}{\sigma_q \sigma_i} \sum_{jk} jk(e_{jk} - q^o_j q^i_k)$$

for directed ones. Here $q^o_i = \sum_j e_{ij}$, $q^i_i = \sum_j e_{ji}$, moreover, $\sigma_q$, $\sigma_o$ and $\sigma_i$ are the standard deviations of $q$, $q^o$ and $q^i$, respectively.

The reason of the difference is that in directed networks the relationship is not symmetric, so it is possible to assign different values to the outgoing and the incoming end of the edges.

assortativity.degree uses vertex degree (minus one) as vertex values and calls assortativity.

Value

A single real number.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

References

Examples

```python
# random network, close to zero
assortativity.degree(erdos.renyi.game(10000, 3/10000))

# BA model, tends to be dissortative
assortativity.degree(ba.game(10000, m=4))
```
attributes

Graph, vertex and edge attributes

**Description**

Attributes are associated values belonging to a graph, vertices or edges. These can represent some property, like data about how the graph was constructed, the color of the vertices when the graph is plotted, or simply the weights of the edges in a weighted graph.

**Usage**

- `get.graph.attribute(graph, name)`
- `set.graph.attribute(graph, name, value)`
- `list.graph.attributes(graph)`
- `graph.attributes(graph)`
- `remove.graph.attribute(graph, name)`
- `get.vertex.attribute(graph, name)`
- `set.vertex.attribute(graph, name, index=V(graph), value)`
- `remove.vertex.attribute(graph, name)`
- `list.vertex.attributes(graph)`
- `vertex.attributes(graph)`
- `get.edge.attribute(graph, name, index=E(graph))`
- `set.edge.attribute(graph, name, index=E(graph), value)`
- `remove.edge.attribute(graph, name)`
- `list.edge.attributes(graph)`
- `edge.attributes(graph)`

**Arguments**

- **graph**
  The graph object to work on. Note that the original graph is never modified, a new graph object is returned instead; if you don’t assign it to a variable your modifications will be lost! See examples below.

- **name**
  Character constant, the name of the attribute.

- **index**
  Numeric vector, the ids of the vertices or edges. It is not recycled, even if `value` is longer.

- **value**
  Numeric vector, the new value(s) of the attributes, it will be recycled if needed.

**Details**

There are three types of attributes in igraph: graph, vertex and edge attributes. Graph attributes are associated with graph, vertex attributes with vertices and edge attributes with edges.

Examples for graph attributes are the date when the graph data was collected or other types of memos like the type of the data, or whether the graph is a simple graph, ie. one without loops and multiple edges.

Examples of vertex attributes are vertex properties, like the vertex coordinates for the visualization of the graph, or other visualization parameters, or meta-data associated with the vertices, like the
gender and the age of the individuals in a friendship network, the type of the neurons in a graph representing neural circuitry or even some pre-computed structural properties, like the betweenness centrality of the vertices.

Examples of edge attributes are data associated with edges: most commonly edge weights, or visualization parameters.

In recent igraph versions, arbitrary R objects can be assigned as graph, vertex or edge attributes. Some igraph functions use the values or graph, vertex and edge attributes if they are present but this is not done in the current version very extensively. Expect more in the (near) future.

Graph attributes can be created with the `set.graph.attribute` function, and removed with `remove.graph.attribute`. Graph attributes are queried with `get.graph.attribute` and the assigned graph attributes are listed with `list.graph.attributes`.

The function `graph.attributes` returns all graph attributes in a named list. This function has a counterpart that sets all graph attributes at once, see an example below.

There is a simpler notation for using graph attributes: the `'$'` operator. It can be used both to query and set graph attributes, see an example below.

The functions for vertex attributes are `set.vertex.attribute`, `get.vertex.attribute`, `remove.vertex.attribute` and `list.vertex.attributes` and for edge attributes they are `set.edge.attribute`, `get.edge.attribute`, `remove.edge.attribute` and `list.edge.attributes`.

Similarly to graph attributes, `vertex.attributes` returns all vertex attributes, in a named list, and `edge.attributes` returns all edge attributes, in a named list.

There is however a (syntactically) much simpler way to handle vertex and edge attribute by using vertex and edge selectors, it works like this: `V(g)` selects all vertices in a graph, and `V(g)$name` queries the `name` attribute for all vertices. Similarly is `vs` is a vertex set `vs$name` gives the values of the `name` attribute for the vertices in the vertex set.

This form can also be used to set the values of the attributes, like the regular R convention:

```
V(g)$color <- "red"
```

It works for vertex subsets as well:

```
V(g)[1:5]$color <- "green"
```

The notation for edges is similar: `E(g)` means all edges `E(g)$weight` is the weight attribute for all edges, etc.

See also the manual page for `iterators` about how to create various vertex and edge sets.

**Value**

`get.graph.attribute`, `get.vertex.attribute` and `get.edge.attribute` return an R object, or a list of R objects if attributes of more vertices/edges are requested.

`set.graph.attribute`, `set.vertex.attribute`, `set.edge.attribute`, and also `remove.graph.attribute`, `remove.vertex.attribute` and `remove.edge.attribute` return a new graph object with the updates/removes performed.

`list.graph.attributes`, `list.vertex.attributes` and `list.edge.attributes` return a character vector, the names of the attributes present.
Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

See Also

`print.igraph` can print attributes. See `attribute.combination` for details on how igraph combines attributes if several vertices or edges are mapped into one.

Examples

```r
# g <- graph.ring(10)
g <- set.graph.attribute(g, "name", "RING")
# It is the same as
g$name <- "RING"
g$name

g <- set.vertex.attribute(g, "color", value=c("red", "green"))
get.vertex.attribute(g, "color")

# The following notation is more convenient
# g <- graph.star(10)
g <- set.edge.attribute(g, "weight", value=runif(ecount(g)))
get.edge.attribute(g, "weight")

str(g, g=TRUE, v=TRUE, e=TRUE)
# Setting all attributes at once
g2 <- graph.empty(10)
g2

graph.attributes(g2) <- graph.attributes(g)
vertex.attributes(g2) <- vertex.attributes(g)
edge.attributes(g2) <- list()
g2

e.edge.attributes(g2) <- list(weight=numeric())
g2
```

---

`autocurve.edges`  
Optimal edge curvature when plotting graphs
autocurve.edges

Description

If graphs have multiple edges, then drawing them as straight lines does not show them when plotting the graphs; they will be on top of each other. One solution is to bend the edges, with different curvature, so that all of them are visible.

Usage

autocurve.edges (graph, start = 0.5)

Arguments

graph The input graph.
start The curvature at the two extreme edges. All edges will have a curvature between -start and start, spaced equally.

Details

autocurve.edges calculates the optimal edge.curved vector for plotting a graph with multiple edges, so that all edges are visible.

Value

A numeric vector, its length is the number of edges in the graph.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

See Also

igraph.plotting for all plotting parameters, plot.igraph, tkplot and rglplot for plotting functions.

Examples

g <- graph( c(0,1,1,0,1,2,1,3,1,3,1,3,2,3,2,3,2,3,0,1)+1 )

autocurve.edges(g)

## Not run:
set.seed(42)
plot(g)

## End(Not run)
**Description**

The BA-model is a very simple stochastic algorithm for building a graph.

**Usage**

```r
barabasi.game(n, power = 1, m = NULL, out.dist = NULL, out.seq = NULL, 
out.pref = FALSE, zero.appeal = 1, directed = TRUE, 
algorithm = c("psumtree", "psumtree-multiple", "bag"), 
start.graph = NULL)
```

**Arguments**

- `n`: Number of vertices.
- `power`: The power of the preferential attachment, the default is one, i.e., linear preferential attachment.
- `m`: Numeric constant, the number of edges to add in each time step. This argument is only used if both `out.dist` and `out.seq` are omitted or NULL.
- `out.dist`: Numeric vector, the distribution of the number of edges to add in each time step. This argument is only used if the `out.seq` argument is omitted or NULL.
- `out.seq`: Numeric vector giving the number of edges to add in each time step. Its first element is ignored as no edges are added in the first time step.
- `out.pref`: Logical, if true the total degree is used for calculating the citation probability, otherwise the in-degree is used.
- `zero.appeal`: The ‘attractiveness’ of the vertices with no adjacent edges. See details below.
- `directed`: Whether to create a directed graph.
- `algorithm`: The algorithm to use for the graph generation. `psumtree` uses a partial prefix-sum tree to generate the graph, this algorithm can handle any power and zero.appeal values and never generates multiple edges. `psumtree-multiple` also uses a partial prefix-sum tree, but the generation of multiple edges is allowed. Before the 0.6 version igraph used this algorithm if `power` was not one, or `zero.appeal` was not one. `bag` is the algorithm that was previously (before version 0.6) used if `power` and `zero.appeal` are equal one.
- `start.graph`: NULL or an igraph graph. If a graph, then the supplied graph is used as a starting graph for the preferential attachment algorithm. The graph should have at least one vertex. If a graph is supplied here and the `out.seq` argument is not NULL, then it should contain the out degrees of the new vertices only, not the ones in the `start.graph`. 
Details

This is a simple stochastic algorithm to generate a graph. It is a discrete time step model and in each time step a single vertex is added.

We start with a single vertex and no edges in the first time step. Then we add one vertex in each time step and the new vertex initiates some edges to old vertices. The probability that an old vertex is chosen is given by

\[ P[i] \sim k_i^\alpha + a \]

where \( k_i \) is the in-degree of vertex \( i \) in the current time step (more precisely the number of adjacent edges of \( i \) which were not initiated by \( i \) itself) and \( \alpha \) and \( a \) are parameters given by the power and zero.appeal arguments.

The number of edges initiated in a time step is given by the \( m, \text{out.dist} \) and \( \text{out.seq} \) arguments. If \( \text{out.seq} \) is given and not NULL then it gives the number of edges to add in a vector, the first element is ignored, the second is the number of edges to add in the second time step and so on. If \( \text{out.seq} \) is not given or null and \( \text{out.dist} \) is given and not NULL then it is used as a discrete distribution to generate the number of edges in each time step. Its first element is the probability that no edges will be added, the second is the probability that one edge is added, etc. (\( \text{out.dist} \) does not need to sum up to one, it normalized automatically.) \( \text{out.dist} \) should contain non-negative numbers and at east one element should be positive.

If both \( \text{out.seq} \) and \( \text{out.dist} \) are omitted or NULL then \( m \) will be used, it should be a positive integer constant and \( m \) edges will be added in each time step.

\texttt{barabasi.game} generates a directed graph by default, set \texttt{directed} to \texttt{FALSE} to generate an undirected graph. Note that even if an undirected graph is generated \( k_i \) denotes the number of adjacent edges not initiated by the vertex itself and not the total (in- + out-) degree of the vertex, unless the \texttt{out.pref} argument is set to \texttt{TRUE}.

Value

A graph object.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

References

\texttt{random.graph.game}

Examples

\begin{verbatim}
g <- barabasi.game(10000)
degree.distribution(g)
\end{verbatim}
betweenness  

Vertex and edge betweenness centrality

Description

The vertex and edge betweenness are (roughly) defined by the number of geodesics (shortest paths) going through a vertex or an edge.

Usage

betweenness(graph, v=V(graph), directed = TRUE, weights = NULL, nobigint = TRUE, normalized = FALSE)
edge.betweenness(graph, e=E(graph), directed = TRUE, weights = NULL)
betweenness.estimate(graph, vids = V(graph), directed = TRUE, cutoff, weights = NULL, nobigint = TRUE)
edge.betweenness.estimate(graph, e=E(graph), directed = TRUE, cutoff, weights = NULL)

Arguments

- **graph**: The graph to analyze.
- **v**: The vertices for which the vertex betweenness will be calculated.
- **e**: The edges for which the edge betweenness will be calculated.
- **directed**: Logical, whether directed paths should be considered while determining the shortest paths.
- **weights**: Optional positive weight vector for calculating weighted betweenness. If the graph has a weight edge attribute, then this is used by default.
- **nobigint**: Logical scalar, whether to use big integers during the calculation. This is only required for lattice-like graphs that have very many shortest paths between a pair of vertices. If TRUE (the default), then big integers are not used.
- **normalized**: Logical scalar, whether to normalize the betweenness scores. If TRUE, then the results are normalized according to

\[ B^n = \frac{2B}{n^2 - 3n + 2} \]

, where \( B^n \) is the normalized, \( B \) the raw betweenness, and \( n \) is the number of vertices in the graph.
- **vids**: The vertices for which the vertex betweenness estimation will be calculated.
- **cutoff**: The maximum path length to consider when calculating the betweenness. If zero or negative then there is no such limit.
betweenness

Details

The vertex betweenness of vertex \( v \) is defined by

\[
\sum_{i \neq j, j 
eq v, j 
eq v} g_{ivj} / g_{ij}
\]

The edge betweenness of edge \( e \) is defined by

\[
\sum_{i \neq j} g_{iej} / g_{ij}.
\]

betweenness calculates vertex betweenness, edge.betweenness calculates edge.betweenness. betweenness.estimate only considers paths of length cutoff or smaller, this can be run for larger graphs, as the running time is not quadratic (if cutoff is small). If cutoff is zero or negative then the function calculates the exact betweenness scores.

generate.betweenness.estimate is similar, but for edges.

For calculating the betweenness a similar algorithm to the one proposed by Brandes (see References) is used.

Value

A numeric vector with the betweenness score for each vertex in \( v \) for betweenness.

A numeric vector with the edge betweenness score for each edge in \( e \) for edge.betweenness.

betweenness.estimate returns the estimated betweenness scores for vertices in \( vIds \), edge.betweenness.estimate the estimated edge betweenness score for all edges; both in a numeric vector.

Note

edge.betweenness might give false values for graphs with multiple edges.

  betweenness(g)
  edge.betweenness(g)
```

---

**biconnected.components**

*Biconnected components*

**Description**

Finding the biconnected components of a graph

**Usage**

```r
  biconnected.components(graph)
```

**Arguments**

- `graph` The input graph. It is treated as an undirected graph, even if it is directed.

**Details**

A graph is biconnected if the removal of any single vertex (and its adjacent edges) does not disconnect it.

A biconnected component of a graph is a maximal biconnected subgraph of it. The biconnected components of a graph can be given by the partition of its edges: every edge is a member of exactly one biconnected component. Note that this is not true for vertices: the same vertex can be part of many biconnected components.

**Value**

A named list with three components:

- `no` Numeric scalar, an integer giving the number of biconnected components in the graph.
- `tree_edges` The components themselves, a list of numeric vectors. Each vector is a set of edge ids giving the edges in a biconnected component. These edges define a spanning tree of the component.
- `component_edges` A list of numeric vectors. It gives all edges in the components.
- `components` A list of numeric vectors, the vertices of the components.
- `articulation_points` The articulation points of the graph. See `articulation.points`.
bipartite.mapping

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

See Also

articulation.points, clusters, is.connected, vertex.connectivity

Examples

```r
# An example bipartite graph
bip <- graph.full(5) %du% graph.full(5)

# Add edges between the two components
bip <- add.edges(bip, 1:5, 6:10)

# Check if the graph is bipartite
bipartite.mapping(bip)
```

Description

This function decides whether the vertices of a network can be mapped to two vertex types in a way that no vertices of the same type are connected.

Usage

```r
bipartite.mapping(graph)
```

Arguments

- `graph`: The input graph.

Details

A bipartite graph in igraph has a `type` vertex attribute giving the two vertex types. This function simply checks whether a graph could be bipartite. It tries to find a mapping that gives a possible division of the vertices into two classes, such that no two vertices of the same class are connected by an edge.

The existence of such a mapping is equivalent of having no circuits of odd length in the graph. A graph with loop edges cannot be bipartite.

Note that the mapping is not necessarily unique, e.g. if the graph has at least two components, then the vertices in the separate components can be mapped independently.

Value

A named list with two elements:

- `res`: A logical scalar, TRUE if the graph can be bipartite, FALSE otherwise.
- `type`: A possibly vertex type mapping, a logical vector. If no such mapping exists, then an empty vector.
Examples

## A ring has just one loop, so it is fine
```r
g <- graph.ring(10)
bipartite.mapping(g)
```

## A star is fine, too
```r
g2 <- graph.star(10)
bipartite.mapping(g2)
```

## A graph containing a triangle is not fine
```r
g3 <- graph.ring(10)
g3 <- add.edges(g3, c(1,3))
bipartite.mapping(g3)
```

---

**bipartite.projection**  
Project a bipartite graph

Description

A bipartite graph is projected into two one-mode networks

Usage

```r
bipartite.projection.size(graph, types = NULL)
bipartite.projection (graph, types = NULL, multiplicity = TRUE, 
probe1 = NULL, which=c("both", "true", "false"), 
remove.type = TRUE)
```

Arguments

- `graph`  
The input graph. It can be directed, but edge directions are ignored during the computation.

- `types`  
An optional vertex type vector to use instead of the `type` vertex attribute. You must supply this argument if the graph has no `type` vertex attribute.

- `multiplicity`  
If TRUE, then igraph keeps the multiplicity of the edges as an edge attribute. E.g. if there is an A-C-B and also an A-D-B triple in the bipartite graph (but no more X, such that A-X-B is also in the graph), then the multiplicity of the A-B edge in the projection will be 2.

- `probe1`  
This argument can be used to specify the order of the projections in the resulting list. If given, then it is considered as a vertex id (or a symbolic vertex name); the projection containing this vertex will be the first one in the result list. This argument is ignored if only one projection is requested in argument `which`.
which A character scalar to specify which projection(s) to calculate. The default is to calculate both.

remove.type Logical scalar, whether to remove the type vertex attribute from the projections. This makes sense because these graphs are not bipartite any more. However if you want to combine them with each other (or other bipartite graphs), then it is worth keeping this attribute. By default it will be removed.

Details

Bipartite graphs have a type vertex attribute in igraph, this is boolean and FALSE for the vertices of the first kind and TRUE for vertices of the second kind.

bipartite.projection.size calculates the number of vertices and edges in the two projections of the bipartite graphs, without calculating the projections themselves. This is useful to check how much memory the projections would need if you have a large bipartite graph.

bipartite.projections calculates the actual projections. You can use the probe1 argument to specify the order of the projections in the result. By default vertex type FALSE is the first and TRUE is the second.

bipartite.projections keeps vertex attributes.

Value

A list of two undirected graphs. See details above.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

Examples

## Projection of a full bipartite graph is a full graph

```r
g <- graph.full.bipartite(10, 5)
proj <- bipartite.projection(g)
graph.isomorphic(proj[[1]], graph.full(10))
graph.isomorphic(proj[[2]], graph.full(5))
```

## The projection keeps the vertex attributes

```r
M <- matrix(0, nr=5, nc=3)
rownames(M) <- c("Alice", "Bob", "Cecil", "Dan", "Ethel")
colnames(M) <- c("Party", "Skiing", "Badminton")
M[] <- sample(0:1, length(M), replace=TRUE)
M
g2 <- graph.incidence(M)
g2$name <- "Event network"
proj2 <- bipartite.projection(g2)
print(proj2[[1]], g=TRUE, e=TRUE)
print(proj2[[2]], g=TRUE, e=TRUE)
```
bipartite.random.game  Bipartite random graphs

Description
Generate bipartite graphs using the Erdos-Renyi model

Usage
bipartite.random.game(n1, n2, type = c("gnp", "gnm"), p, m,
directed = FALSE, mode = c("out", "in", "all"))

Arguments
- **n1**: Integer scalar, the number of bottom vertices.
- **n2**: Integer scalar, the number of top vertices.
- **type**: Character scalar, the type of the graph, ‘gnp’ creates a $G(n,p)$ graph, ‘gnm’ creates a $G(n,m)$ graph. See details below.
- **p**: Real scalar, connection probability for $G(n,p)$ graphs. Should not be given for $G(n,m)$ graphs.
- **m**: Integer scalar, the number of edges for $G(n,p)$ graphs. Should not be given for $G(n,m)$ graphs.
- **directed**: Logical scalar, whether to create a directed graph. See also the mode argument.
- **mode**: Character scalar, specifies how to direct the edges in directed graphs. If it is ‘out’, then directed edges point from bottom vertices to top vertices. If it is ‘in’, edges point from top vertices to bottom vertices. ‘out’ and ‘in’ do not generate mutual edges. If this argument is ‘all’, then each edge direction is considered independently and mutual edges might be generated. This argument is ignored for undirected graphs.

Details
Similarly to unipartite (one-mode) networks, we can define the $G(n,p)$, and $G(n,m)$ graph classes for bipartite graphs, via their generating process. In $G(n,p)$ every possible edge between top and bottom vertices is realized with probability $p$, independently of the rest of the edges. In $G(n,m)$, we uniformly choose $m$ edges to realize.

Value
A bipartite igraph graph.

Author(s)
Gabor Csardi <csardi.gabor@gmail.com>
**bonpow**

**See Also**

[erdos.renyi.game](#) for the unipartite version.

**Examples**

```r
## empty graph
bipartite.random.game(10, 5, p=0)

## full graph
bipartite.random.game(10, 5, p=1)

## random bipartite graph
bipartite.random.game(10, 5, p=.1)

## directed bipartite graph, G(n,m)
bipartite.random.game(10, 5, type="Gnm", m=20, directed=TRUE, mode="all")
```

---

**bonpow**  
*Find Bonacich Power Centrality Scores of Network Positions*

**Description**

`bonpow` takes a graph (`dat`) and returns the Boncich power centralities of positions (selected by `nodes`). The decay rate for power contributions is specified by `exponent` (1 by default).

**Usage**

```r
bonpow(graph, nodes=V(graph), loops=FALSE, exponent=1, rescale=FALSE, tol=1e-7, sparse=TRUE)
```

**Arguments**

- **graph**  
  the input graph.

- **nodes**  
  vertex sequence indicating which vertices are to be included in the calculation. By default, all vertices are included.

- **loops**  
  boolean indicating whether or not the diagonal should be treated as valid data. Set this true if and only if the data can contain loops. `loops` is `FALSE` by default.

- **exponent**  
  exponent (decay rate) for the Bonacich power centrality score; can be negative

- **rescale**  
  if true, centrality scores are rescaled such that they sum to 1.

- **tol**  
  tolerance for near-singularities during matrix inversion (see `solve`)

- **sparse**  
  Logical scalar, whether to use sparse matrices for the calculation. The ‘Matrix’ package is required for sparse matrix support
Details

Bonacich’s power centrality measure is defined by $C_{BP}(\alpha, \beta) = \alpha (I - \beta A)^{-1} A1$, where $\beta$ is an attenuation parameter (set here by exponent) and $A$ is the graph adjacency matrix. (The coefficient $\alpha$ acts as a scaling parameter, and is set here (following Bonacich (1987)) such that the sum of squared scores is equal to the number of vertices. This allows 1 to be used as a reference value for the “middle” of the centrality range.) When $\beta \to 1/\lambda_{A1}$ (the reciprocal of the largest eigenvalue of $A$), this is to within a constant multiple of the familiar eigenvector centrality score; for other values of $\beta$, the behavior of the measure is quite different. In particular, $\beta$ gives positive and negative weight to even and odd walks, respectively, as can be seen from the series expansion $C_{BP}(\alpha, \beta) = \alpha \sum_{k=0}^{\infty} \beta^k A^{k+1} 1$ which converges so long as $|\beta| < 1/\lambda_{A1}$. The magnitude of $\beta$ controls the influence of distant actors on ego’s centrality score, with larger magnitudes indicating slower rates of decay. (High rates, hence, imply a greater sensitivity to edge effects.)

Interpretively, the Bonacich power measure corresponds to the notion that the power of a vertex is recursively defined by the sum of the power of its alters. The nature of the recursion involved is then controlled by the power exponent: positive values imply that vertices become more powerful as their alters become more powerful (as occurs in cooperative relations), while negative values imply that vertices become more powerful only as their alters become weaker (as occurs in competitive or antagonistic relations). The magnitude of the exponent indicates the tendency of the effect to decay across long walks; higher magnitudes imply slower decay. One interesting feature of this measure is its relative instability to changes in exponent magnitude (particularly in the negative case). If your theory motivates use of this measure, you should be very careful to choose a decay parameter on a non-ad hoc basis.

Value

A vector, containing the centrality scores.

Warning

Singular adjacency matrices cause no end of headaches for this algorithm; thus, the routine may fail in certain cases. This will be fixed when I get a better algorithm. bonpow will not symmetrize your data before extracting eigenvectors; don’t send this routine asymmetric matrices unless you really mean to do so.

Note

This function was ported (ie. copied) from the SNA package.

 canonical.permutation  Canonical permutation of a graph

Description

The canonical permutation brings every isomorphic graphs into the same (labeled) graph.

Usage

canonical.permutation(graph, sh="fm")

Arguments

graph  The input graph, treated as undirected.
sh  Type of the heuristics to use for the BLISS algorithm. See details for possible values.
Details

canonical.permutation computes a permutation which brings the graph into canonical form, as defined by the BLISS algorithm. All isomorphic graphs have the same canonical form.

See the paper below for the details about BLISS. This and more information is available at http://www.tcs.hut.fi/Software/bliss/index.html.

The possible values for the \texttt{sh} argument are:

\begin{itemize}
\item \texttt{f} First non-singleton cell.
\item \texttt{fl} First largest non-singleton cell.
\item \texttt{fs} First smallest non-singleton cell.
\item \texttt{fm} First maximally non-trivially connected non-singleton cell.
\item \texttt{flm} Largest maximally non-trivially connected non-singleton cell.
\item \texttt{fsn} Smallest maximally non-trivially connected non-singleton cell.
\end{itemize}

See the paper in references for details about these.

Value

A list with the following members:

- \texttt{labeling} The canonical permutation which takes the input graph into canonical form. A numeric vector, the first element is the new label of vertex 0, the second element for vertex 1, etc.
- \texttt{info} Some information about the BLISS computation. A named list with the following members:
  - \texttt{nof\_nodes} The number of nodes in the search tree.
  - \texttt{nof\_leaf\_nodes} The number of leaf nodes in the search tree.
  - \texttt{nof\_bad\_nodes} Number of bad nodes.
  - \texttt{nof\_canupdates} Number of canrep updates.
  - \texttt{max\_level} Maximum level.
  - \texttt{group\_size} The size of the automorphism group of the input graph, as a string. This number is exact if igraph was compiled with the GMP library, and approximate otherwise.

### centralization

**Centralization of a graph**

**Description**

Centralization is a method for creating a graph level centralization measure from the centrality scores of the vertices.

**Usage**

- `centralize.scores(scores, theoretical.max, normalized = TRUE)`
- `centralization.degree(graph, mode = c("all", "out", "in", "total"), loops = TRUE, normalized = TRUE)`
- `centralization.closeness(graph, mode = c("out", "in", "all", "total"), normalized = TRUE)`
- `centralization.betweenness(graph, directed = TRUE, nobigint = TRUE, normalized = TRUE)`
- `centralization.evcent(graph, directed = FALSE, scale = TRUE, options = igraph.arpack.default, normalized = TRUE)`
- `centralization.degree.tmax(graph = NULL, nodes = 0, mode = c("all", "out", "in", "total"), loops = FALSE)`
- `centralization.closeness.tmax(graph = NULL, nodes = 0, mode = c("out", "in", "all", "total"))`
centralization.betweenness.tmax (graph = NULL, nodes = 0, directed = TRUE)
centralization.evcent.tmax (graph = NULL, nodes = 0, directed = FALSE, scale = TRUE)

Arguments

scores The vertex level centrality scores.
theoretical.max Real scalar. The graph level centrality score of the most centralized graph with the same number of vertices as the graph under study. This is only used if the normalized argument is set to TRUE.
normalized Logical scalar. Whether to normalize the graph level centrality score by dividing the supplied theoretical maximum.
graph The input graph. For the “tmax” functions it can be NULL, see the details below.
mode This is the same as the mode argument of degree and closeness.
loops Logical scalar, whether to consider loops edges when calculating the degree.
directed logical scalar, whether to use directed shortest paths for calculating betweenness.
nobigint Logical scalar, whether to use big integers for the betweenness calculation. This argument is passed to the betweenness function.
scale Whether to rescale the eigenvector centrality scores, such that the maximum score is one.
nodes The number of vertices. This is ignored if the graph is given.
options This is passed to evcent, the options for the ARPACK eigensolver.

Details

Centralization is a general method for calculating a graph-level centrality score based on node-level centrality measure. The formula for this is

$$ C(G) = \sum_v (\max_w c_{w} - c_v), $$

where $c_v$ is the centrality of vertex $v$.

The graph-level centrality score can be normalized by dividing by the maximum theoretical score for a graph with the same number of vertices, using the same parameters, e.g. directedness, whether we consider loop edges, etc.

For degree, closeness and betweenness the most centralized structure is some version of the star graph, in-star, out-star or undirected star.

For eigenvector centrality the most centralized structure is the graph with a single edge (and potentially many isolates).

centralize.scores using the general centralization formula to calculate a graph-level score from vertex-level scores.
centralization

centralization.degree, centralization.closeness, centralization.betweenness calculate both the vertex-level and the graph-level indices.

centralization.degree.tmax, centralization.closeness.tmax, centralization.betweenness.tmax and centralization.evcent.tmax return the theoretical maximum scores. They operate in two modes. In the first mode, a graph is given and the maximum score is calculated based on that. E.g. the number of vertices and directedness is taken from this graph.

The other way to call these functions is to omit the graph argument, but explicitly specify the rest of the arguments.

Value

For centralize.scores a real scalar.

For centralization.degree, centralization.closeness and centralization.betweenness a named list with the following components:

res The node-level centrality scores.
centralization The graph level centrality index.
theoretical_max The maximum theoretical graph level centralization score for a graph with the given number of vertices, using the same parameters. If the normalized argument was TRUE, then the result was divided by this number.

For centralization.evcent a named list with the following components:

vector The node-level centrality scores.
value The corresponding eigenvalue.
opts ARPACK options, see the return value of evcent for details.
centralization The graph level centrality index.
theoretical_max The same as above, the theoretical maximum centralization score for a graph with the same number of vertices.

For centralization.degree.tmax, centralization.closeness.tmax, centralization.betweenness.tmax and centralization.evcent.tmax a real scalar.

**cliques**

*The functions find cliques, i.e. complete subgraphs in a graph*

**Description**

These functions find all, the largest or all the maximal cliques in an undirected graph. The size of the largest clique can also be calculated.

**Usage**

cliques(graph, min=NULL, max=NULL)  
largest.cliques(graph)  
maximal.cliques(graph, min=NULL, max=NULL, subset=NULL, file=NULL)  
maximal.cliques.count(graph, min=NULL, max=NULL, subset=NULL)  
clique.number(graph)

**Arguments**

- **graph**: The input graph, directed graphs will be considered as undirected ones, multiple edges and loops are ignored.
- **min**: Numeric constant, lower limit on the size of the cliques to find. NULL means no limit, i.e. it is the same as 0.
- **max**: Numeric constant, upper limit on the size of the cliques to find. NULL means no limit.
- **subset**: If not NULL, then it must be a vector of vertex ids, numeric or symbolic if the graph is named. The algorithm is run from these vertices only, so only a subset of all maximal cliques is returned. See the Eppstein paper for details. This argument makes it possible to easily parallelize the finding of maximal cliques.
- **file**: If not NULL, then it must be a file name, i.e. a character scalar. The output of the algorithm is written to this file. (If it exists, then it will be overwritten.) Each clique will be a separate line in the file, given with the numeric ids of its vertices, separated by whitespace.
cliques

Details

cliques find all complete subgraphs in the input graph, obeying the size limitations given in the min and max arguments.

largest.clques finds all largest cliques in the input graph. A clique is largest if there is no other clique including more vertices.

maximal.clques finds all maximal cliques in the input graph. A clique in maximal if it cannot be extended to a larger clique. The largest cliques are always maximal, but a maximal clique is not necessarily the largest.

maximal.clques.count counts the maximal cliques.

clique.number calculates the size of the largest clique(s).

The current implementation of these functions searches for maximal independent vertex sets (see independent.vertex.sets) in the complemener graph.

Value

cliques, largest.clques and clique.number return a list containing numeric vectors of vertex ids. Each list element is a clique.

maximal.clques returns NULL, invisibly, if its file argument is not NULL. The output is written to the specified file in this case.

clique.number and maximal.clques.count return an integer scalar.

# To have a bit less maximal cliques, about 100-200 usually

g <- erdos.renyi.game(100, 0.03)
maximal.clques(g)
closeness

Closeness centrality of vertices

Description

Closeness centrality measures how many steps is required to access every other vertex from a given vertex.

Usage

closeness(graph, vids=V(graph), mode = c("out", "in", "all", "total"),
weights = NULL, normalized = FALSE)
closeness.estimate(graph, vids=V(graph), mode = c("out", "in", "all", "total"),
cutoff, weights = NULL, normalized = FALSE)

Arguments

graph The graph to analyze.
vids The vertices for which closeness will be calculated.
mode Character string, defined the types of the paths used for measuring the distance in directed graphs. “in” measures the paths to a vertex, “out” measures paths from a vertex, all uses undirected paths. This argument is ignored for undirected graphs.
normalized Logical scalar, whether to calculate the normalized closeness. Normalization is performed by multiplying the raw closeness by $n - 1$, where $n$ is the number of vertices in the graph.
cutoff The maximum path length to consider when calculating the betweenness. If zero or negative then there is no such limit.
weights Optional positive weight vector for calculating weighted closeness. If the graph has a weight edge attribute, then this is used by default.

Details

The closeness centrality of a vertex is defined by the inverse of the average length of the shortest paths to/from all the other vertices in the graph:

$$\frac{1}{\sum_{i \neq v} d_{v,i}}$$

If there is no (directed) path between vertex $v$ and $i$ then the total number of vertices is used in the formula instead of the path length.

closeness.estimate only considers paths of length cutoff or smaller, this can be run for larger graphs, as the running time is not quadratic (if cutoff is small). If cutoff is zero or negative then the function calculates the exact closeness scores.
**Clusters**

**Description**

Calculate the maximal (weakly or strongly) connected components of a graph

**Value**

Numeric vector with the closeness values of all the vertices in \( v \).

**Author(s)**

Gabor Csardi <csardi.gabor@gmail.com>

**References**

**See Also**

`betweenness`, `degree`

**Examples**

```r
g <- graph.ring(10)
g2 <- graph.star(10)
closeness(g)
closeness(g2, mode="in")
closeness(g2, mode="out")
closeness(g2, mode="all")
```

---

**Clusters**  
*Connected components of a graph*

**Description**

Calculate the maximal (weakly or strongly) connected components of a graph

**Usage**

```r
is_connected(graph, mode=c("weak", "strong"))
clusters(graph, mode=c("weak", "strong"))
no.clusters(graph, mode=c("weak", "strong"))
cluster_distribution(graph, cumulative = FALSE, mul.size = FALSE, ...)
```

**Arguments**

- `graph`  
The graph to analyze.
- `mode`  
Character string, either “weak” or “strong”. For directed graphs “weak” implies weakly, “strong” strongly connected components to search. It is ignored for undirected graphs.
- `cumulative`  
Logical, if TRUE the cumulative distribution (relative frequency) is calculated.
- `mul.size`  
Logical. If TRUE the relative frequencies will be multiplied by the cluster sizes.
- `...`  
Additional attributes to pass to `cluster`, right now only `mode` makes sense.
Details

is.connected decides whether the graph is weakly or strongly connected.
clusters finds the maximal (weakly or strongly) connected components of a graph.
no.clusters does almost the same as clusters but returns only the number of clusters found instead of returning the actual clusters.
cluster.distribution creates a histogram for the maximal connected component sizes.
The weakly connected components are found by a simple breadth-first search. The strongly connected components are implemented by two consecutive depth-first searches.

Value

For is.connected a logical constant.
For clusters a named list with three components:

- membership numeric vector giving the cluster id to which each vertex belongs.
- csize numeric vector giving the sizes of the clusters.
- no numeric constant, the number of clusters.

For no.clusters an integer constant is returned.
For cluster.distribution a numeric vector with the relative frequencies. The length of the vector is the size of the largest component plus one. Note that (for currently unknown reasons) the first element of the vector is the number of clusters of size zero, so this is always zero.

g <- erdos.renyi.game(20, 1/20)
clusters(g)

cocitation Cocitation coupling

Description

Two vertices are cocited if there is another vertex citing both of them. cocitation simply counts how many types two vertices are cocited. The bibliographic coupling of two vertices is the number of other vertices they both cite, bibcoupling calculates this.
**Usage**

```r
cocitation(graph, v=V(graph))
bibcoupling(graph, v=V(graph))
```

**Arguments**

- `graph`  
  The graph object to analyze

- `v`  
  Vertex sequence or numeric vector, the vertex ids for which the cocitation or bibliographic coupling values we want to calculate. The default is all vertices.

**Details**

- `cocitation` calculates the cocitation counts for the vertices in the `v` argument and all vertices in the graph.

- `bibcoupling` calculates the bibliographic coupling for vertices in `v` and all vertices in the graph.

Calculating the cocitation or bibliographic coupling for only one vertex costs the same amount of computation as for all vertices. This might change in the future.

**Value**

A numeric matrix with `length(v)` lines and `vcount(graph)` columns. Element `(i,j)` contains the cocitation or bibliographic coupling for vertices `v[i]` and `j`.

**Author(s)**

Gabor Csardi <csardi.gabor@gmail.com>

**Examples**

```r
g <- graph.ring(10)
cocitation(g)
bibcoupling(g)
```

---

**cohesive.blocks**  
*Calculate Cohesive Blocks*

**Description**

Calculates cohesive blocks for objects of class `igraph`.
Usage

cohesive.blocks(graph, labels = TRUE)

blocks(blocks)
blockGraphs(blocks, graph)
cohesion(blocks)
hierarchy(blocks)
parent(blocks)
plotHierarchy(blocks,
   layout = layout.reingold.tilford(hierarchy(blocks), root=1), ...)
exportPajek(blocks, graph, file, project.file = TRUE)
maxcohesion(blocks)

## S3 method for class 'cohesiveBlocks'
print(x, ...)
## S3 method for class 'cohesiveBlocks'
summary(object, ...)
## S3 method for class 'cohesiveBlocks'
length(x)
## S3 method for class 'cohesiveBlocks'
plot(x, y, colbar = rainbow(max(cohesion(x))+1),
   col = colbar[maxcohesion(x)+1], mark.groups = blocks(x)[-1], ...)

Arguments

graph For cohesive.blocks a graph object of class igraph. It must be undirected and simple. (See is.simple.)
For blockGraphs and exportPajek the same graph must be supplied whose cohesive block structure is given in the blocks argument.

labels Logical scalar, whether to add the vertex labels to the result object. These labels can be then used when reporting and plotting the cohesive blocks.

blocks,x,object A cohesiveBlocks object, created with the cohesive.blocks function.

file Defines the file (or connection) the Pajek file is written to.
If the project.file argument is TRUE, then it can be a filename (with extension), a file object, or in general any kind of connection object. The file/connection will be opened if it wasn’t already.
If the project.file argument is FALSE, then several files are created and file must be a character scalar containing the base name of the files, without extension. (But it can contain the path to the files.)
See also details below.

project.file Logical scalar, whether to create a single Pajek project file containing all the data, or to create separated files for each item. See details below.

y The graph whose cohesive blocks are supplied in the x argument.
colbar Color bar for the vertex colors. Its length should be at least \( m + 1 \), where \( m \) is the maximum cohesion in the graph. Alternatively, the vertex colors can also be directly specified via the col argument.
cohesive.blocks

**col**
A vector of vertex colors, in any of the usual formats. (Symbolic color names (e.g. ‘red’, ‘blue’, etc.) , RGB colors (e.g. ‘#FF9900FF’), integer numbers referring to the current palette. By default the given colbar is used and vertices with the same maximal cohesion will have the same color.

**mark.groups**
A list of vertex sets to mark on the plot by circling them. By default all cohesive blocks are marked, except the one corresponding to the all vertices.

**layout**
The layout of a plot, it is simply passed on to plot.igraph, see the possible formats there. By default the Reingold-Tilford layout generator is used.

**...**
Additional arguments. plotHierarchy and plot pass them to plot.igraph. print and summary ignore them.

**Details**

Cohesive blocking is a method of determining hierarchical subsets of graph vertices based on their structural cohesion (or vertex connectivity). For a given graph $G$, a subset of its vertices $S \subset V(G)$ is said to be maximally $k$-cohesive if there is no superset of $S$ with vertex connectivity greater than or equal to $k$. Cohesive blocking is a process through which, given a $k$-cohesive set of vertices, maximally $l$-cohesive subsets are recursively identified with $l > k$. Thus a hierarchy of vertex subsets is found, with the entire graph $G$ at its root.

The function cohesive.blocks implements cohesive blocking. It returns a cohesiveBlocks object. cohesiveBlocks should be handled as an opaque class, i.e. its internal structure should not be accessed directly, but through the functions listed here.

The function length can be used on cohesiveBlocks objects and it gives the number of blocks.

The function blocks returns the actual blocks stored in the cohesiveBlocks object. They are returned in a list of numeric vectors, each containing vertex ids.

The function blockGraphs is similar, but returns the blocks as (induced) subgraphs of the input graph. The various (graph, vertex and edge) attributes are kept in the subgraph.

The function cohesion returns a numeric vector, the cohesion of the different blocks. The order of the blocks is the same as for the blocks and blockGraphs functions.

The block hierarchy can be queried using the hierarchy function. It returns an igraph graph, its vertex ids are ordered according the order of the blocks in the blocks and blockGraphs, cohesion, etc. functions.

parent gives the parent vertex of each block, in the block hierarchy, for the root vertex it gives 0.

plotHierarchy plots the hierarchy tree of the cohesive blocks on the active graphics device, by calling igraph.plot.

The export.Pajek function can be used to export the graph and its cohesive blocks in Pajek format. It can either export a single Pajek project file with all the information, or a set of files, depending on its project.file argument. If project.file is TRUE, then the following information is written to the file (or connection) given in the file argument: (1) the input graph, together with its attributes, see write.graph for details; (2) the hierarchy graph; and (3) one binary partition for each cohesive block. If project.file is FALSE, then the file argument must be a character scalar and it is used as the base name for the generated files. If file is ‘basename’, then the following files are created: (1) ‘basename.net’ for the original graph; (2) ‘basename_hierarchy.net’ for the hierarchy graph; (3) ‘basename_block_x.net’ for each cohesive block, where ‘x’ is the number of the block, starting with one.
maxcohesion returns the maximal cohesion of each vertex, i.e. the cohesion of the most cohesive block of the vertex.

The generic function summary works on cohesiveBlocks objects and it prints a one line summary to the terminal.

The generic function print is also defined on cohesiveBlocks objects and it is invoked automatically if the name of the cohesiveBlocks object is typed in. It produces an output like this:

```
Cohesive block structure:
B-1       c 1, n 23
 ' - B-2   c 2, n 14 oooooooo...o......oo 000
 ' - B-4   c 5, n  7 oooooooo...............
 ' - B-3   c 2, n 10 ......0.00 0.000000... ...
 ' - B-5   c 3, n  4 ......0.00 0............  
```

The left part shows the block structure, in this case for five blocks. The first block always corresponds to the whole graph, even if its cohesion is zero. Then cohesion of the block and the number of vertices in the block are shown. The last part is only printed if the display is wide enough and shows the vertices in the blocks, ordered by vertex ids. ‘o’ means that the vertex is included, a dot means that it is not, and the vertices are shown in groups of ten.

The generic function plot plots the graph, showing one or more cohesive blocks in it.

**Value**

- cohesive.blocks returns a cohesiveBlocks object.
- blocks returns a list of numeric vectors, containing vertex ids.
- blockGraphs returns a list of igraph graphs, corresponding to the cohesive blocks.
- cohesion returns a numeric vector, the cohesion of each block.
- hierarchy returns an igraph graph, the representation of the cohesive block hierarchy.
- parent returns a numeric vector giving the parent block of each cohesive block, in the block hierarchy. The block at the root of the hierarchy has no parent and 0 is returned for it.
- plotHierarchy, plot and exportPajek return NULL, invisibly.
- maxcohesion returns a numeric vector with one entry for each vertex, giving the cohesion of its most cohesive block.
- print and summary return the cohesiveBlocks object itself, invisibly.
- length returns a numeric scalar, the number of blocks.

**Author(s)**

Gabor Csardi <csardi.gabor@gmail.com> for the current implementation, Peter McMahan (http://home.uchicago.edu/~mcmahan/) wrote the first version in R.

Combining attributes

How igraph functions handle attributes when the graph changes

Description

Many times, when the structure of a graph is modified, vertices/edges map of the original graph map to vertices/edges in the newly created (modified) graph. For example \texttt{simplify} maps multiple edges to single edges. igraph provides a flexible mechanism to specify what to do with the vertex/edge attributes in these cases.

Details

The functions that support the combination of attributes have one or two extra arguments called \texttt{vertex.attr.comb} and/or \texttt{edge.attr.comb} that specify how to perform the mapping of the attributes. E.g. \texttt{contract.vertices} contracts many vertices into a single one, the attributes of the vertices can be combined and stores as the vertex attributes of the new graph.

The specification of the combination of (vertex or edge) attributes can be given as

1. a character scalar,
2. a function object or
3. a list of character scalars and/or function objects.

If it is a character scalar, then it refers to one of the predefined combinations, see their list below.

If it is a function, then the given function is expected to perform the combination. It will be called once for each new vertex/edge in the graph, with a single argument: the attribute values of the vertices that map to that single vertex.

The third option, a list can be used to specify different combination methods for different attributes. A named entry of the list corresponds to the attribute with the same name. An unnamed entry (i.e. if the name is the empty string) of the list specifies the default combination method. I.e.

\begin{verbatim}
list(weight="sum", "ignore")
\end{verbatim}

specifies that the weight of the new edge should be sum of the weights of the corresponding edges in the old graph; and that the rest of the attributes should be ignored (=dropped).

Predefined combination functions

The following combination behaviors are predefined:

\begin{description}
\item[ignore] The attribute is ignored and dropped.
\item[sum] The sum of the attributes is calculated. This does not work for character attributes and works for complex attributes only if they have a \texttt{sum} generic defined. (E.g. it works for sparse matrices from the Matrix package, because they have a \texttt{sum} method.)
\item[prod] The product of the attributes is calculated. This does not work for character attributes and works for complex attributes only if they have a \texttt{prod} function defined.
\end{description}
Combining attributes

‘min’ The minimum of the attributes is calculated and returned. For character and complex attributes the standard R \texttt{min} function is used.

‘max’ The maximum of the attributes is calculated and returned. For character and complex attributes the standard R \texttt{max} function is used.

‘random’ Chooses one of the supplied attribute values, uniformly randomly. For character and complex attributes this is implemented by calling \texttt{sample}.

‘first’ Always chooses the first attribute value. It is implemented by calling the \texttt{head} function.

‘last’ Always chooses the last attribute value. It is implemented by calling the \texttt{tail} function.

‘mean’ The mean of the attributes is calculated and returned. For character and complex attributes this simply calls the \texttt{mean} function.

‘median’ The median of the attributes is selected. Calls the R \texttt{median} function for all attribute types.

‘concat’ Concatenate the attributes, using the \texttt{c} function. This results almost always a complex attribute.

Specifying combination methods for all graphs

The are two standard igraph parameters that define the default behavior when combining vertices and edges: \texttt{vertex.attr.comb} specifies how to combine vertices by default, \texttt{edge.attr.comb} does the same for edges.

E.g. if you want to drop all vertex attributes when combining vertices, you can specify

\begin{verbatim}
igraph.options(vertex.attr.comb="ignore")
\end{verbatim}

As another example, if – when combining edges – you want to keep the mean weight of the edges, concatenate their names into a single character scalar, and drop everything else, then use

\begin{verbatim}
igraph.options(edge.attr.comb=list(weight="mean",
   name=toString, "ignore")
\end{verbatim}

Simple and complex attributes

An attribute is simple if (for all vertices/edges) it can be specified as an atomic vector. Character and numeric attributes are always simple. E.g. a vertex attribute that is a numeric vector of arbitrary length for each vertex, is a complex attribute.

Combination of attributes might turn a complex attribute into a single one, and the opposite is possible, too. E.g. when concatenating attribute values to form the new attribute value, the result will be typically a complex attribute.

\texttt{attributes} on how to use graph/vertex/edges attributes in general. \texttt{igraph.options} on igraph parameters.
Examples

g <- graph( c(1,2, 1,2, 1,2, 2,3, 3,4) )
E(g)$weight <- 1:5

## print attribute values with the graph
igraph.options(print.graph.attributes=TRUE)
igraph.options(print.vertex.attributes=TRUE)
igraph.options(print.edge.attributes=TRUE)

## new attribute is the sum of the old ones
simplify(g, edge.attr.comb="sum")

## collect attributes into a string
simplify(g, edge.attr.comb=toString)

## concatenate them into a vector, this creates a complex
## attribute
simplify(g, edge.attr.comb="concat")

E(g)$name <- letters[seq_len(ecount(g))]

## both attributes are collected into strings
simplify(g, edge.attr.comb=toString)

## harmonic average of weights, names are dropped
simplify(g, edge.attr.comb=list(weight=function(x) length(x)/sum(1/x),
                                 name="ignore"))

---

## communities

Functions to deal with the result of network community detection

Description

igraph community detection functions return their results as an object from the `communities` class. This manual page describes the operations of this class.

Usage

## S3 method for class 'communities'
print(x, ...)

## S3 method for class 'communities'
length(x)

## S3 method for class 'communities'
sizes(communities)

## S3 method for class 'communities'
membership(communities)

## S3 method for class 'communities'
modularity(x, ...)

## S3 method for class 'communities'
algorithm(communities)
crossing(communities, graph)

is.hierarchical(communities, full = FALSE)
merges(communities)
cutat(communities, no, steps)
## S3 method for class 'communities'
as.dendrogram(object, hang=-1,
   use.modularity=FALSE, ...)
## S3 method for class 'communities'
as.hclust(x, hang = -1,
   use.modularity = FALSE, ...)
## S3 method for class 'communities'
asPhylo(x, use.modularity=FALSE, ...)
showtrace(communities)

code.length(communities)

## S3 method for class 'communities'
plot(x, y,
   colbar=rainbow(length(x)),
   col=colbar[membership(x)],
   mark.groups=communities(x),
   edge.color=c("black", "red")[crossing(x,y)+1],
   ...)

create.communities(membership, algorithm = NULL, merges = NULL,
   modularity = NULL, ...)

Arguments

communities,x,object
   A communities object, the result of an igraph community detection function.

graph
   An igraph graph object, corresponding to communities.

full
   Logical scalar, if TRUE, then is.hierarchical only returns TRUE for fully hier-
   archical algorithms. The ‘leading eigenvector’ algorithm is hierarchical, it gives
   a hierarchy of groups, but not a full dendrogram with all vertices, so it is not
   fully hierarchical.

y
   An igraph graph object, corresponding to the communities in x.

no
   Integer scalar, the desired number of communities. If too low or two high, then
   an error message is given. Exactly one of no and steps must be supplied.

steps
   The number of merge operations to perform to produce the communities. Ex-
  actly one of no and steps must be supplied.

colbar
   A vector of colors, in any format that is accepted by the regular R plotting meth-
   ods. E.g. it may be an integer vector, a character vector of color names, a
   character vector of RGB colors. This vector gives the color bar for the vertices.
   The length of the vector should be the same as the number of communities.
col
A vector of colors, in any format that is accepted by the regular R plotting methods. This vector gives the colors of the vertices explicitly.

mark.groups
A list of numeric vectors. The communities can be highlighted using colored polygons. The groups for which the polygons are drawn are given here. The default is to use the groups given by the communities. Supply NULL here if you do not want to highlight any groups.

edge.color
The colors of the edges. By default the edges within communities are colored green and other edges are red.

hang
Numeric scalar indicating how the height of leaves should be computed from the heights of their parents; see plot.hclust.

use.modularity
Logical scalar, whether to use the modularity values to define the height of the branches.

... Additional arguments. plot.communities passes these to plot.igraph. create.communities adds them to the communities object it creates. The other functions silently ignore them.

membership
Numeric vector, one value for each vertex, the membership vector of the community structure.

algorithm
If not NULL (meaning an unknown algorithm), then a character scalar, the name of the algorithm that produced the community structure.

merges
If not NULL, then the merge matrix of the hierarchical community structure. See merges below for more information on its format.

modularity
Numeric scalar or vector, the modularity value of the community structure. It can also be NULL, if the modularity of the (best) split is not available.

Details
Community structure detection algorithms try to find dense subgraphs in directed or undirected graphs, by optimizing some criteria, and usually using heuristics.

igraph implements a number of community detection methods (see them below), all of which return an object of the class communities. Because the community structure detection algorithms are different, communities objects do not always have the same structure. Nevertheless, they have some common operations, these are documented here.

The print generic function is defined for communities, it prints a short summary.

The length generic function call be called on communities and returns the number of communities.

The sizes function returns the community sizes, in the order of their ids.

membership gives the division of the vertices, into communities. It returns a numeric vector, one value for each vertex, the id of its community. Community ids start from one. Note that some algorithms calculate the complete (or incomplete) hierarchical structure of the communities, and not just a single partitioning. For these algorithms typically the membership for the highest modularity value is returned, but see also the manual pages of the individual algorithms.

modularity gives the modularity score of the partitioning. (See modularity.igraph for details. For algorithms that do not result a single partitioning, the highest modularity value is returned.

algorithm gives the name of the algorithm that was used to calculate the community structure.
crossing returns a logical vector, with one value for each edge, ordered according to the edge ids. The value is TRUE iff the edge connects two different communities, according to the (best) membership vector, as returned by membership().

is.hierarchical checks whether a hierarchical algorithm was used to find the community structure. Some functions only make sense for hierarchical methods (e.g. merges, cutat and as.dendrogram).

merges returns the merge matrix for hierarchical methods. An error message is given, if a non-hierarchical method was used to find the community structure. You can check this by calling is.hierarchical on the communities object.

cutat cuts the merge tree of a hierarchical community finding method, at the desired place and returns a membership vector. The desired place can be expressed as the desired number of communities or as the number of merge steps to make. The function gives an error message, if called with a non-hierarchical method.

as.dendrogram converts a hierarchical community structure to a dendrogram object. It only works for hierarchical methods, and gives an error message to others. See dendrogram for details.

as.hclust is similar to as.dendrogram, but converts a hierarchical community structure to a hclust object.

asPhylo converts a hierarchical community structure to a phylo object, you will need the ape package for this.

showtrace works (currently) only for communities found by the leading eigenvector method (leading.eigenvector.community) and returns a character vector that gives the steps performed by the algorithm while finding the communities.

code.length is defined for the InfoMAP method (infomap.community) and returns the code length of the partition.

It is possibly to call the plot function on communities objects. This will plot the graph (and uses plot.igraph internally), with the communities shown. By default it colores the vertices according to their communities, and also marks the vertex groups corresponding to the communities. It passes additional arguments to plot.igraph, please see that and also igraph.plotting on how to change the plot.

create.communities creates a communities object. This is useful to integrate the results of community finding algorithms (that are not included in igraph).

Value

print returns the communities object itself, invisibly.

length returns an integer scalar.

sizes returns a numeric vector.

membership returns a numeric vector, one number for each vertex in the graph that was the input of the community detection.

modularity returns a numeric scalar.

algorithm returns a character scalar.

crossing returns a logical vector.

is.hierarchical returns a logical scalar.

merges returns a two-column numeric matrix.
community.to.membership

cutat returns a numeric vector, the membership vector of the vertices.
as.dendrogram returns a dendrogram object.
showtrace returns a character vector.
code.length returns a numeric scalar for communities found with the InfoMAP method and NULL for other methods.
plot for communities objects returns NULL, invisibly.
create.communities objects returns a communities object.

karate <- graph.famous("Zachary")
w <- walktrap.community(karate)
modularity(w)
membership(w)
plot(w, karate)

community.to.membership

Common functions supporting community detection algorithms

Description

community.to.membership takes a merge matrix, a typical result of community structure detection algorithms and creates a membership vector by performing a given number of merges in the merge matrix.

Usage

community.to.membership(graph, merges, steps, membership=TRUE, csize=TRUE)
Arguments

graph  The graph to which the merge matrix belongs.
merges The merge matrix, see e.g. walktrap.community for the exact format.
steps  The number of steps, ie. merges to be performed.
membership Logical scalar, whether to include the membership vector in the result.
csize  Logical scalar, whether to include the sizes of the communities in the result.

Value

A named list with two members:

membership  The membership vector.
csize        A numeric vector giving the sizes of the communities.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

See Also

walktrap.community, edge.betweenness.community, fastgreedy.community, spinglass.community
for various community detection methods.

Examples

```r
library(igraph)

# Create a graph
G <- graph.full(5) %du% graph.full(5) %du% graph.full(5)
G <- add.edges(G, c(1, 6, 1, 11, 6, 11))
wtc <- walktrap.community(G)
community.to.membership(G, wtc$merges, steps=12)
```

---

**Description**

This function assesses the distance between two community structures.

**Usage**

```r
## S3 method for class 'communities'
compare(comm1, comm2, method = c(“vi”, “nmi”,
  “split.join”, “rand”,
  “adjusted.rand”))

## S3 method for class 'numeric'
compare(comm1, comm2, method = c(“vi”, “nmi”,
  “split.join”, “rand”,
  “adjusted.rand”))
```
Arguments

comm1 A `communities` object containing a community structure; or a numeric vector, the membership vector of the first community structure. The membership vector should contain the community id of each vertex, the numbering of the communities starts with one.

comm2 A `communities` object containing a community structure; or a numeric vector, the membership vector of the second community structure, in the same format as for the previous argument.

method Character scalar, the comparison method to use. Possible values: ‘vi’ is the variation of information (VI) metric of Meila (2003), ‘nmi’ is the normalized mutual information measure proposed by Danon et al. (2005), ‘split.join’ is the split-join distance of van Dongen (2000), ‘rand’ is the Rand index of Rand (1971), ‘adjusted.rand’ is the adjusted Rand index by Hubert and Arabie (1985).

Value

A real number.

g <- graph.famous("Zachary")
sg <- spinglass.community(g)
le <- leading.eigenvector.community(g)
```
In- or out- component of a vertex

Description

Finds all vertices reachable from a given vertex, or the opposite: all vertices from which a given vertex is reachable via a directed path.

Usage

```r
subcomponent(graph, v, mode = c("all", "out", "in"))
```

Arguments

- `graph` The graph to analyze.
- `v` The vertex to start the search from.
- `mode` Character string, either “in”, “out” or “all”. If “in” all vertices from which `v` is reachable are listed. If “out” all vertices reachable from `v` are returned. If “all” returns the union of these. It is ignored for undirected graphs.

Details

A breadth-first search is conducted starting from vertex `v`.

Value

Numeric vector, the ids of the vertices in the same component as `v`.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

`clusters`

Examples

```r
g <- erdos.renyi.game(100, 1/200)
subcomponent(g, 1, "in")
subcomponent(g, 1, "out")
subcomponent(g, 1, "all")
```
Description

Given a graph, `constraint` calculates Burt’s constraint for each vertex.

Usage

```r
constraint(graph, nodes=V(graph), weights=NULL)
```

Arguments

- `graph`: A graph object, the input graph.
- `nodes`: The vertices for which the constraint will be calculated. Defaults to all vertices.
- `weights`: The weights of the edges. If this is `NULL` and there is a `weight` edge attribute this is used. If there is no such edge attribute all edges will have the same weight.

Details

Burt’s constraint is higher if ego has less, or mutually stronger related (i.e. more redundant) contacts. Burt’s measure of constraint, $C_i$, of vertex $i$’s ego network $V_i$, is defined for directed and valued graphs,

$$
C_i = \sum_{j \in V_i \setminus \{i\}} (p_{ij} + \sum_{q \in V_i \setminus \{i,j\}} p_{iq}p_{qj})^2
$$

for a graph of order (i.e. number of vertices) $N$, where proportional tie strengths are defined as

$$
p_{ij} = \frac{a_{ij} + a_{ji}}{\sum_{k \in V_i \setminus \{i\}} (a_{ik} + a_{ki})},
$$

$a_{ij}$ are elements of $A$ and the latter being the graph adjacency matrix. For isolated vertices, constraint is undefined.

Value

A numeric vector of constraint scores

contract.vertices  Contract several vertices into a single one

Description
This function creates a new graph, by merging several vertices into one. The vertices in the new
graph correspond to sets of vertices in the input graph.

Usage
contract.vertices(graph, mapping,
vertex.attr.comb=getIgraphOpt("vertex.attr.comb"))

Arguments
graph        The input graph, it can be directed or undirected.
mapping      A numeric vector that specifies the mapping. Its elements correspond to the
vertices, and for each element the id in the new graph is given.
vertex.attr.comb
             Specifies how to combine the vertex attributes in the new graph. Please see
attribute.combination for details.

Details
The attributes of the graph are kept. Graph and edge attributes are unchanged, vertex attributes are
combined, according to the vertex.attr.comb parameter.

Value
A new graph object.

Author(s)
Gabor Csardi <csardi.gabor@gmail.com>

Examples
k <- graph.ring(10)
g$name <- "Ring"
V(g)$name <- letters[1:Vcount(g)]
E(g)$weight <- runif(Ecount(g))
g2 <- contract.vertices(g, rep(1:5, each=2),
vertex.attr.comb=toString)
## conversion

**Convert a graph to an adjacency matrix or an edge list**

### Description

Sometimes it is useful to have a standard representation of a graph, like an adjacency matrix or an edge list.

### Usage

```r
get.adjacency(graph, type=c("both", "upper", "lower"),
             attr=NULL, edges=FALSE, names=TRUE,
             sparse=getigraphOpt("sparsematrices"))
get.edgelist(graph, names=TRUE)
```

### Arguments

- **graph**
  The graph to convert.

- **type**
  Gives how to create the adjacency matrix for undirected graphs. It is ignored for directed graphs. Possible values: upper: the upper right triangle of the matrix is used, lower: the lower left triangle of the matrix is used. both: the whole matrix is used, a symmetric matrix is returned.

- **attr**
  Either NULL or a character string giving an edge attribute name. If NULL a traditional adjacency matrix is returned. If not NULL then the values of the given edge attribute are included in the adjacency matrix. If the graph has multiple edges, the edge attribute of an arbitrarily chosen edge (for the multiple edges) is included. This argument is ignored if edges is TRUE.

  Note that this works only for certain attribute types. If the sparse argument is TRUE, then the attribute must be either logical or numeric. If the sparse argument is FALSE, then character is also allowed. The reason for the difference is that the Matrix package does not support character sparse matrices yet.

- **edges**
  Logical scalar, whether to return the edge ids in the matrix. For non-existant edges zero is returned.

- **names**
  Logical constant.

  For graph.adjacency it gives whether to assign row and column names to the matrix. These are only assigned if the name vertex attribute is present in the graph.

  for get.edgelist it gives whether to return a character matrix containing vertex names (i.e. the name vertex attribute) if they exist or numeric vertex ids.

- **sparse**
  Logical scalar, whether to create a sparse matrix. The ‘Matrix’ package must be installed for creating sparse matrices.
Details

get.adjacency returns the adjacency matrix of a graph, a regular R matrix if sparse is FALSE, or a sparse matrix, as defined in the ‘Matrix’ package, if sparse if TRUE.

get.edgelist returns the list of edges in a graph.

Value

A vcount(graph) by vcount(graph) (usually) numeric matrix for get.adjacency. (This can be huge!) Note that a non-numeric matrix might be returned if attr is a non-numeric edge attribute.

A ecount(graph) by 2 numeric matrix for get.edgelist.

graph.adjacency, read.graph

Examples

g <- erdos.renyi.game(10, 2/10)
get.edgelist(g)
get.adjacency(g)
V(g)$name <- letters[1:vcount(g)]
get.adjacency(g)
E(g)$weight <- runif(ecount(g))
get.adjacency(g, attr="weight")

Description

The graphNEL class is defined in the graph package, it is another way to represent graphs. These functions are provided to convert between the igraph and the graphNEL objects.

Usage

igraph.from.graphNEL(graphNEL, name = TRUE, weight = TRUE,
unlist.attrs = TRUE)
igraph.to.graphNEL(graph)
conversion between igraph and graphNEL graphs

Arguments

- **graphNEL**: The graphNEL graph.
- **name**: Logical scalar, whether to add graphNEL vertex names as an igraph vertex attribute called ‘name’.
- **weight**: Logical scalar, whether to add graphNEL edge weights as an igraph edge attribute called ‘weight’. (graphNEL graphs are always weighted.)
- **unlist.attrs**: Logical scalar. graphNEL attribute query functions return the values of the attributes in R lists, if this argument is TRUE (the default) these will be converted to atomic vectors, whenever possible, before adding them to the igraph graph.
- **graph**: An igraph graph object.

Details

igraph.from.graphNEL takes a graphNEL graph and converts it to an igraph graph. It handles all graph/vertex/edge attributes. If the graphNEL graph has a vertex attribute called ‘name’ it will be used as igraph vertex attribute ‘name’ and the graphNEL vertex names will be ignored.

Because graphNEL graphs poorly support multiple edges, the edge attributes of the multiple edges are lost: they are all replaced by the attributes of the first of the multiple edges.

igraph.to.graphNEL converts and igraph graph to a graphNEL graph. It converts all graph/vertex/edge attributes. If the igraph graph has a vertex attribute ‘name’, then it will be used to assign vertex names in the graphNEL graph. Otherwise igraph vertex ids will be used for this purpose.

Value

- **igraph.from.graphNEL**: returns an igraph graph object.
- **igraph.to.graphNEL**: returns a graphNEL graph object.

Examples

```r
### Undirected
g <- graph.ring(10)
V(g)$name <- letters[1:10]
GNEL <- igraph.to.graphNEL(g)
g2 <- igraph.from.graphNEL(GNEL)
g2

### Directed
g3 <- graph.star(10, mode="in")
V(g3)$name <- letters[1:10]
GNEL2 <- igraph.to.graphNEL(g3)
```
convex.hull

convex.hull <- igraph.from.graphNEL(GNEL2)
g4

Description

Calculate the convex hull of a set of points, i.e. the covering polygon that has the smallest area.

Usage

convex.hull(data)

Arguments

data

The data points, a numeric matrix with two columns.

Value

A named list with components:

resverts

The indices of the input vertices that constitute the convex hull.

rescoords

The coordinates of the corners of the convex hull.

Author(s)

Tamas Nepusz <ntamas@gmail.com>

convex.hull(M)
**decompose.graph**

*Decompose a graph into components*

**Description**

Creates a separate graph for each component of a graph.

**Usage**

```r
decompose.graph(graph, mode = c("weak", "strong"),
               max.comps = NA, min.vertices = 0)
```

**Arguments**

- **graph**: The original graph.
- **mode**: Character constant giving the type of the components, either `weak` for weakly connected components or `strong` for strongly connected components.
- **max.comps**: The maximum number of components to return. The first `max.comps` components will be returned (which hold at least `min.vertices` vertices, see the next parameter), the others will be ignored. Supply `NA` here if you don’t want to limit the number of components.
- **min.vertices**: The minimum number of vertices a component should contain in order to place it in the result list. Eg. supply 2 here to ignore isolate vertices.

**Value**

A list of graph objects.

**Author(s)**

Gabor Csardi <csardi.gabor@gmail.com>

**See Also**

- `is.connected` to decide whether a graph is connected, `clusters` to calculate the connected components of a graph.

**Examples**

```r
# the diameter of each component in a random graph
g <- erdos.renyi.game(1000, 1/1000)
comps <- decompose.graph(g, min.vertices=2)
sapply(comps, diameter)
```
**Description**

The degree of a vertex is its most basic structural property, the number of its adjacent edges.

**Usage**

```r
degree(graph, v=V(graph), mode = c("all", "out", "in", "total"),
      loops = TRUE, normalized = FALSE)
degree.distribution(graph, cumulative = FALSE, ...)
```

**Arguments**

- `graph`: The graph to analyze.
- `v`: The ids of vertices of which the degree will be calculated.
- `mode`: Character string. "out" for out-degree, "in" for in-degree or "total" for the sum of the two. For undirected graphs this argument is ignored. "all" is a synonym of "total".
- `loops`: Logical; whether the loop edges are also counted.
- `normalized`: Logical scalar, whether to normalize the degree. If TRUE then the result is divided by \( n - 1 \), where \( n \) is the number of vertices in the graph.
- `cumulative`: Logical; whether the cumulative degree distribution is to be calculated.
- `...`: Additional arguments to pass to `degree`, eg. `mode` is useful but also `v` and `loops` make sense.

**Value**

- For `degree` a numeric vector of the same length as argument `v`.
- For `degree.distribution` a numeric vector of the same length as the maximum degree plus one. The first element is the relative frequency zero degree vertices, the second vertices with degree one, etc.

**Author(s)**

Gabor Csardi <csardi.gabor@gmail.com>

**Examples**

```r
g <- graph.ring(10)
degree(g)
g2 <- erdos.renyi.game(1000, 10/1000)
degree.distribution(g2)
```
Generate random graphs with a given degree sequence

Description

It is often useful to create a graph with given vertex degrees. This is exactly what `degree.sequence.game` does.

Usage

```
degree.sequence.game(out.deg, in.deg = NULL,
    method = c("simple", "vl", "simple.no.multiple"), ...)
```

Arguments

- `out.deg`: Numeric vector, the sequence of degrees (for undirected graphs) or out-degrees (for directed graphs). For undirected graphs its sum should be even. For directed graphs its sum should be the same as the sum of `in.deg`.
- `in.deg`: For directed graph, the in-degree sequence. By default this is `NULL` and an undirected graph is created.
- `method`: Character, the method for generating the graph. Right now the “simple”, “simple.no.multiple” and “vl” methods are implemented.
- `...`: Additional arguments, these are used as graph attributes.

Details

The “simple” method connects the out-stubs of the edges (undirected graphs) or the out-stubs and in-stubs (directed graphs) together. This way loop edges and also multiple edges may be generated. This method is not adequate if one needs to generate simple graphs with a given degree sequence. The multiple and loop edges can be deleted, but then the degree sequence is distorted and there is nothing to ensure that the graphs are sampled uniformly.

The “simple.no.multiple” method is similar to “simple”, but tries to avoid multiple and loop edges and restarts the generation from scratch if it gets stuck. It is not guaranteed to sample uniformly from the space of all possible graphs with the given sequence, but it is relatively fast and it will eventually succeed if the provided degree sequence is graphical, but there is no upper bound on the number of iterations.

The “vl” method is a more sophisticated generator. The algorithm and the implementation was done by Fabien Viger and Matthieu Latapy. This generator always generates undirected, connected simple graphs, it is an error to pass the `in.deg` argument to it. The algorithm relies on first creating an initial (possibly unconnected) simple undirected graph with the given degree sequence (if this is possible at all). Then some rewiring is done to make the graph connected. Finally a Monte-Carlo algorithm is used to randomize the graph. The “vl” samples from the undirected, connected simple graphs uniformly. See `http://www-rp.lip6.fr/~latapy/FV/generation.html` for details.
dendPlot

Value

The new graph object.

dendPlot  

Plot dendrograms

Description

This is generic function that can plot various objects as dendrograms.
Details

Currently the function is defined for communities (see `dendPlot.communities`) and igraphHRG (see `dendPlot.igraphHRG`) objects.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

Examples

```r
karate <- graph.famous("Zachary")
fc <- fastgreedy.community(karate)
dendPlot(fc)
```

---

**dendPlot.communities**  Community structure dendrogram plots

Description

Plot a hierarchical community structure as a dendrogram.

Usage

```r
## S3 method for class 'communities'
dendPlot(x, mode = getigraphOpt("dend.plot.type"),
          ..., use.modularity = FALSE)
```

Arguments

- `x`: An object containing the community structure of a graph. See `communities` for details.
- `mode`: Which dendrogram plotting function to use. See details below.
- `...`: Additional arguments to supply to the dendrogram plotting function.
- `use.modularity`: Logical scalar, whether to use the modularity values to define the height of the branches.

Details

dendPlot supports three different plotting functions, selected via the `mode` argument. By default the plotting function is taken from the `dend.plot.type` igraph option, and it has for possible values:

- `auto`: Choose automatically between the plotting functions. As `plot.phylo` is the most sophisticated, that is choosen, whenever the ape package is available. Otherwise `plot.hclust` is used.
- `phylo`: Use `plot.phylo` from the ape package.
- `hclust`: Use `plot.hclust` from the stats package.
• dendrogram Use plot.dendrogram from the stats package.

The different plotting functions take different sets of arguments. When using plot.phylo (mode="phylo"), we have the following syntax:

```r
dendPlot(x, mode="phylo",
colbar = rainbow(11, start=0.7, end=0.1),
edge.color = NULL, use.edge.length = FALSE, ...)
```

The extra arguments not documented above:

- colbar Color bar for the edges.
- edge.color Edge colors. If NULL, then the colbar argument is used.
- use.edge.length Passed to plot.phylo.
- dots Additional arguments to pass to plot.phylo.

The syntax for plot.hclust (mode="hclust"):

```r
dendPlot(x, mode="hclust", rect = 0, colbar = rainbow(rect),
         hang = 0.01, ann = FALSE, main = "", sub = ",", xlab = ",",
ylab = ",", ...)
```

The extra arguments not documented above:

- rect A numeric scalar, the number of groups to mark on the dendrogram. The dendrogram is cut into exactly rect groups and they are marked via the rect.hclust command. Set this to zero if you don't want to mark any groups.
- colbar The colors of the rectangles that mark the vertex groups via the rect argument.
- hang Where to put the leaf nodes, this corresponds to the hang argument of plot.hclust.
- ann Whether to annotate the plot, the ann argument of plot.hclust.
- main The main title of the plot, the main argument of plot.hclust.
- sub The sub-title of the plot, the sub argument of plot.hclust.
- xlab The label on the horizontal axis, passed to plot.hclust.
- ylab The label on the vertical axis, passed to plot.hclust.
- dots Additional arguments to pass to plot.hclust.

The syntax for plot.dendrogram (mode="dendrogram"):

```r
dendPlot(x, ...)
```

The extra arguments are simply passed to as.dendrogram.

**Value**

Returns whatever the return value was from the plotting function, plot.phylo, plot.dendrogram or plot.hclust.
**Author(s)**

Gabor Csardi <csardi.gabor@gmail.com>

**Examples**

```r
karete <- graph.famous("Zachary")
f <- fastgreedy.community(karete)
dendPlot(f)
```

---

**Description**

Plot a hierarchical random graph as a dendrogram.

**Usage**

```r
## S3 method for class 'igraphHRG'
dendPlot(x, mode = getigraphopt("dend.plot.type"),
        ...)  
```

**Arguments**

- `x` An igraphHRG, a hierarchical random graph, as returned by the `hrg.fit` function.
- `mode` Which dendrogram plotting function to use. See details below.
- `...` Additional arguments to supply to the dendrogram plotting function.

**Details**

dendPlot supports three different plotting functions, selected via the `mode` argument. By default the plotting function is taken from the `dend.plot.type` igraph option, and it has for possible values:

- **auto** Choose automatically between the plotting functions. As `plot.phylo` is the most sophisticated, that is choosen, whenever the ape package is available. Otherwise `plot.hclust` is used.
- **phylo** Use `plot.phylo` from the ape package.
- **hclust** Use `plot.hclust` from the stats package.
- **dendrogram** Use `plot.dendrogram` from the stats package.

The different plotting functions take different sets of arguments. When using `plot.phylo` (mode="phylo"), we have the following syntax:

```r
dendPlot(x, mode="phylo",
colbar = rainbow(11, start=0.7, end=0.1),
edge.color = NULL, use.edge.length = FALSE, ...)
```
The extra arguments not documented above:

- colbar Color bar for the edges.
- edge.color Edge colors. If NULL, then the colbar argument is used.
- use.edge.length Passed to plot.phylo.
- dots Additional arguments to pass to plot.phylo.

The syntax for plot.hclust (mode="hclust"):

```r
dendPlot(x, mode="hclust", rect = 0, colbar = rainbow(rect),
    hang = 0.01, ann = FALSE, main = "", sub = ",
    xlab = ",
    ylab = ",...
```

The extra arguments not documented above:

- rect A numeric scalar, the number of groups to mark on the dendrogram. The dendrogram is cut into exactly rect groups and they are marked via the rect.hclust command. Set this to zero if you don’t want to mark any groups.
- colbar The colors of the rectangles that mark the vertex groups via the rect argument.
- hang Where to put the leaf nodes, this corresponds to the hang argument of plot.hclust.
- ann Whether to annotate the plot, the ann argument of plot.hclust.
- main The main title of the plot, the main argument of plot.hclust.
- sub The sub-title of the plot, the sub argument of plot.hclust.
- xlab The label on the horizontal axis, passed to plot.hclust.
- ylab The label on the vertical axis, passed to plot.hclust.
- dots Additional arguments to pass to plot.hclust.

The syntax for plot.dendrogram (mode="dendrogram"):

```r
dendPlot(x, ...)
```

The extra arguments are simply passed to as.dendrogram.

Value

Returns whatever the return value was from the plotting function, plot.phylo, plot.dendrogram or plot.hclust.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

Examples

```r
g <- graph.full(5) + graph.full(5)
hrg <- hrg.fit(g)
dendPlot(hrg)
```
diameter \hspace*{1cm} \textit{Diameter of a graph}

\section*{Description}

The diameter of a graph is the length of the longest geodesic.

\section*{Usage}

\begin{verbatim}
diameter(graph, directed = TRUE, unconnected = TRUE, weights = NULL)
get.diameter (graph, directed = TRUE, unconnected = TRUE, weights = NULL)
farthest.nodes (graph, directed = TRUE, unconnected = TRUE, weights = NULL)
\end{verbatim}

\section*{Arguments}

\begin{itemize}
  \item \textbf{graph}\hspace*{1cm} The graph to analyze.
  \item \textbf{directed}\hspace*{1cm} Logical, whether directed or undirected paths are to be considered. This is ignored for undirected graphs.
  \item \textbf{unconnected}\hspace*{1cm} Logical, what to do if the graph is unconnected. If FALSE, the function will return a number that is one larger the largest possible diameter, which is always the number of vertices. If TRUE, the diameters of the connected components will be calculated and the largest one will be returned.
  \item \textbf{weights}\hspace*{1cm} Optional positive weight vector for calculating weighted distances. If the graph has a weight edge attribute, then this is used by default.
\end{itemize}

\section*{Details}

The diameter is calculated by using a breadth-first search like method.

get.diameter returns a path with the actual diameter. If there are many shortest paths of the length of the diameter, then it returns the first one found.

farthest.nodes returns two vertex ids, the vertices which are connected by the diameter path.

\section*{Value}

A numeric constant for diameter, a numeric vector for get.diameter and a numeric vector of length two for farthest.nodes.

\section*{Author(s)}

Gabor Csardi <csardi.gabor@gmail.com>

\section*{See Also}

**Examples**

```r
library(igraph)

# Create a ring graph
gr <- graph.ring(10)

# Delete edges
gr2 <- delete_edges(gr, c(1,2,1,10))

diameter(gr2, unconnected=TRUE)
diameter(gr2, unconnected=FALSE)

# Weighted diameter
set.seed(1)
gr <- graph.ring(10)
E(gr)$weight <- sample(seq_len(ecount(gr)))
diameter(gr)
get.diameter(gr)
diameter(gr, weights=NA)
diameter(gr, weights=NA)
```

---

**dominator.tree**

**Dominator tree**

**Description**

Dominator tree of a directed graph.

**Usage**

```r
dominator.tree (graph, root, mode = c("out", "in"))
```

**Arguments**

- **graph**
  - A directed graph. If it is not a flowgraph, and it contains some vertices not reachable from the root vertex, then these vertices will be collected and returned as part of the result.

- **root**
  - The id of the root (or source) vertex, this will be the root of the tree.

- **mode**
  - Constant, must be 'in' or 'out'. If it is 'in', then all directions are considered as opposite to the original one in the input graph.

**Details**

A flowgraph is a directed graph with a distinguished start (or root) vertex \( r \), such that for any vertex \( v \), there is a path from \( r \) to \( v \). A vertex \( v \) dominates another vertex \( w \) (not equal to \( v \)), if every path from \( r \) to \( w \) contains \( v \). Vertex \( v \) is the immediate dominator or \( w, v = idom(w) \), if \( v \) dominates \( w \) and every other dominator of \( w \) dominates \( v \). The edges \( (idom(w), w) | w \neq r \) form a directed tree, rooted at \( r \), called the dominator tree of the graph. Vertex \( v \) dominates vertex \( w \) if and only if \( v \) is an ancestor of \( w \) in the dominator tree.

This function implements the Lengauer-Tarjan algorithm to construct the dominator tree of a directed graph. For details see the reference below.
Value

A list with components:

- `dom`: A numeric vector giving the immediate dominators for each vertex. For vertices that are unreachable from the root, it contains NaN. For the root vertex itself it contains minus one.

- `domtree`: A graph object, the dominator tree. Its vertex ids are the as the vertex ids of the input graph. Isolate vertices are the ones that are unreachable from the root.

- `leftout`: A numeric vector containing the vertex ids that are unreachable from the root.

  plot(dtree$domtree, layout=layout, vertex.label=V(dtree$domtree)$name)
}
```

Drawing graphs

Description

The common bits of the three plotting functions `plot.igraph`, `tkplot` and `rglplot` are discussed in this manual page.

Details

There are currently three different functions in the igraph package which can draw graph in various ways:

- `plot.igraph` does simple non-interactive 2D plotting to R devices. Actually it is an implementation of the `plot` generic function, so you can write `plot(graph)` instead of `plot.igraph(graph)`. As it used the standard R devices it supports every output format for which R has an output device.
The list is quite impressive: PostScript, PDF files, XFig files, SVG files, JPG, PNG and of course you can plot to the screen as well using the default devices, or the good-looking anti-aliased Cairo device. See \texttt{plot.igraph} for some more information.

\texttt{tkplot} does interactive 2D plotting using the \texttt{tcltk} package. It can only handle graphs of moderate size, a thousand vertices is probably already too many. Some parameters of the plotted graph can be changed interactively after issuing the \texttt{tkplot} command: the position, color and size of the vertices and the color and width of the edges. See \texttt{tkplot} for details.

\texttt{rglplot} is an experimental function to draw graphs in 3D using OpenGL. See \texttt{rglplot} for some more information.

Please also check the examples below.

\textbf{How to specify graphical parameters}

There are three ways to give values to the parameters described below, in section 'Parameters'. We give these three ways here in the order of their precedence.

The first method is to supply named arguments to the plotting commands: \texttt{plot.igraph}, \texttt{tkplot} or \texttt{rglplot}. Parameters for vertices start with prefix ‘vertex.’, parameters for edges have prefix ‘edge.’, and global parameters have no prefix. Eg. the color of the vertices can be given via argument \texttt{vertex.color}, whereas \texttt{edge.color} sets the color of the edges. \texttt{layout} gives the layout of the graphs.

The second way is to assign vertex, edge and graph attributes to the graph. These attributes have no prefix, ie. the color of the vertices is taken from the \texttt{color} vertex attribute and the color of the edges from the \texttt{color} edge attribute. The layout of the graph is given by the \texttt{layout} graph attribute. (Always assuming that the corresponding command argument is not present.) Setting vertex and edge attributes are handy if you want to assign a given ‘look’ to a graph, attributes are saved with the graph is you save it with \texttt{save} or in GraphML format with \texttt{write.graph}, so the graph will have the same look after loading it again.

If a parameter is not given in the command line, and the corresponding vertex/edge/graph attribute is also missing then the general igraph parameters handled by \texttt{igraph.options} are also checked. Vertex parameters have prefix ‘vertex.’, edge parameters are prefixed with ‘edge.’, general parameters like \texttt{layout} are prefixed with ‘plot’. These parameters are useful if you want all or most of your graphs to have the same look, vertex size, vertex color, etc. Then you don’t need to set these at every plotting, and you also don’t need to assign vertex/edge attributes to every graph.

If the value of a parameter is not specified by any of the three ways described here, its default valued is used, as given in the source code.

Different parameters can have different type, eg. vertex colors can be given as a character vector with color names, or as an integer vector with the color numbers from the current palette. Different types are valid for different parameters, this is discussed in detail in the next section. It is however always true that the parameter can always be a function object in which it will be called with the graph as its single argument to get the “proper” value of the parameter. (If the function returns another function object that will \textit{not} be called again…) 

\textbf{The list of parameters}

Vertex parameters first, note that the ‘vertex.’ prefix needs to be added if they are used as an argument or when setting via \texttt{igraph.options}. The value of the parameter may be scalar valid for every vertex or a vector with a separate value for each vertex. (Shorter vectors are recycled.)

\texttt{plot.igraph}
**size** The size of the vertex, a numeric scalar or vector, in the latter case each vertex sizes may differ. This vertex sizes are scaled in order have about the same size of vertices for a given value for all three plotting commands. It does not need to be an integer number. The default value is 15. This is big enough to place short labels on vertices.

**size2** The “other” size of the vertex, for some vertex shapes. For the various rectangle shapes this gives the height of the vertices, whereas size gives the width. It is ignored by shapes for which the size can be specified with a single number. The default is 15.

**color** The fill color of the vertex. If it is numeric then the current palette is used, see **palette**. If it is a character vector then it may either contain named colors or RGB specified colors with three or four bytes. All strings starting with ‘#’ are assumed to be RGB color specifications. It is possible to mix named color and RGB colors. Note that **tkplot** ignores the fourth byte (alpha channel) in the RGB color specification. If you don’t want (some) vertices to have any color, supply **NA** as the color name. The default value is “SkyBlue2”.

**frame.color** The color of the frame of the vertices, the same formats are allowed as for the fill color. If you don’t want vertices to have a frame, supply **NA** as the color name. By default it is “black”.

**shape** The shape of the vertex, currently “circle”, “square”, “csquare”, “rectangle”, “crectangle”, “vrectangle”, “pie” (see **vertex.shape.pie**), ‘sphere’, and “none” are supported, and only by the **plot.igraph** command. “none” does not draw the vertices at all, although vertex label are plotted (if given). See **igraph.vertex.shapes** for details about vertex shapes and **vertex.shape.pie** for using pie charts as vertices. The “sphere” vertex shape plots vertices as 3D ray-traced spheres, in the given color and size. This produces a raster image and it is only supported with some graphics devices. On some devices raster transparency is not supported and the spheres do not have a transparent background. See **dev.capabilities** and the ‘rasterImage’ capability to check that your device is supported. By default vertices are drawn as circles.

**label** The vertex labels. They will be converted to character. Specify **NA** to omit vertex labels. The default vertex labels are the vertex ids.

**label.family** The font family to be used for vertex labels. As different plotting commands can use different fonts, they interpret this parameter different ways. The basic notation is, however, understood by both **plot.igraph** and **tkplot**. **rglplot** does not support fonts at all right now, it ignores this parameter completely. For **plot.igraph** this parameter is simply passed to **text** as argument **family**. For **tkplot** some conversion is performed. If this parameter is the name of an existing Tk font, then that font is used and the **label.font** and **label.cex** parameters are ignored completely. If it is one of the base families (serif, sans, mono) then Times, Helvetica or Courier fonts are used, there are guaranteed to exist on all systems. For the ‘symbol’ base family we used the symbol font is available, otherwise the first font which has ‘symbol’ in its name. If the parameter is not a name of the base families and it is also not a named Tk font then we pass it to **tkfont.create** and hope the user knows what she is doing. The **label.font** and **label.cex** parameters are also passed to **tkfont.create** in this case. The default value is ‘serif’. 
**label.font**: The font within the font family to use for the vertex labels. It is interpreted the same way as the the `font` graphical parameter: 1 is plain text, 2 is bold face, 3 is italic, 4 is bold and italic and 5 specifies the symbol font.

For `plot.igraph` this parameter is simply passed to `text`.

For `tkplot`, if the `label.family` parameter is not the name of a Tk font then this parameter is used to set whether the newly created font should be italic and/or boldface. Otherwise it is ignored.

For `rglplot` it is ignored.

The default value is 1.

**label.cex**: The font size for vertex labels. It is interpreted as a multiplication factor of some device-dependent base font size.

For `plot.igraph` it is simply passed to `text` as argument `cex`.

For `tkplot` it is multiplied by 12 and then used as the `size` argument for `tkfont.create`. The base font is thus 12 for tkplot.

For `rglplot` it is ignored.

The default value is 1.

**label.dist**: The distance of the label from the center of the vertex. If it is 0 then the label is centered on the vertex. If it is 1 then the label is displayed beside the vertex.

The default value is 0.

**label.degree**: It defines the position of the vertex labels, relative to the center of the vertices. It is interpreted as an angle in radian, zero means ‘to the right’, and ‘\(\pi\)’ means to the left, up is \(\pi/2\) and down is \(-\pi/2\).

The default value is \(-\pi/4\).

**label.color**: The color of the labels, see the `color` vertex parameter discussed earlier for the possible values.

The default value is `black`.

Edge parameters require to add the ‘edge.’ prefix when used as arguments or set by `igraph.options`.

The edge parameters:

**color**: The color of the edges, see the `color` vertex parameter for the possible values.

By default this parameter is `darkgrey`.

**width**: The width of the edges.

The default value is 1.

**arrow.size**: The size of the arrows. Currently this is a constant, so it is the same for every edge. If a vector is submitted then only the first element is used, ie. if this is taken from an edge attribute then only the attribute of the first edge is used for all arrows. This will likely change in the future.

The default value is 1.

**arrow.width**: The width of the arrows. Currently this is a constant, so it is the same for every edge. If a vector is submitted then only the first element is used, ie. if this is taken from an edge attribute then only the attribute of the first edge is used for all arrows. This will likely change in the future.

This argument is currently only used by `plot.igraph`.

The default value is 1, which gives the same width as before this option appeared in igraph.
lty  The line type for the edges. Almost the same format is accepted as for the standard graphics par, 0 and “blank” mean no edges, 1 and “solid” are for solid lines, the other possible values are: 2 (“dashed”), 3 (“dotted”), 4 (“dotdash”), 5 (“longdash”), 6 (“twodash”).

tkplot also accepts standard Tk line type strings, it does not however support “blank” lines, instead of type ‘0’ type ‘1’, i.e. solid lines will be drawn.

This argument is ignored for rglplot.

The default value is type 1, a solid line.

label  The edge labels. They will be converted to character. Specify NA to omit edge labels.

Edge labels are omitted by default.

label.family  Font family of the edge labels. See the vertex parameter with the same name for the details.

label.font  The font for the edge labels. See the corresponding vertex parameter discussed earlier for details.

label.cex  The font size for the edge labels, see the corresponding vertex parameter for details.

label.color  The color of the edge labels, see the color vertex parameters on how to specify colors.

label.x  The horizontal coordinates of the edge labels might be given here, explicitly. The NA elements will be replaced by automatically calculated coordinates. If NULL, then all edge horizontal coordinates are calculated automatically. This parameter is only supported by plotNigraph.

label.y  The same as label.x, but for vertical coordinates.

curved  Specifies whether to draw curved edges, or not. This can be a logical or a numeric vector or scalar.

First the vector is replicated to have the same length as the number of edges in the graph. Then it is interpreted for each edge separately. A numeric value specifies the curvature of the edge; zero curvature means straight edges, negative values means the edge bends clockwise, positive values the opposite. TRUE means curvature 0.5, FALSE means curvature zero.

By default the vector specifying the curvature is calculated via a call to the autocurveNedges function. This function makes sure that multiple edges are curved and are all visible. This parameter is ignored for loop edges.

The default value is FALSE.

This parameter is currently ignored by rglplot.

arrows.mode  This parameter can be used to specify for which edges should arrows be drawn. If this parameter is given by the user (in either of the three ways) then it specifies which edges will have forward, backward arrows, or both, or no arrows at all. As usual, this parameter can be a vector or a scalar value. It can be an integer or character type. If it is integer then 0 means no arrows, 1 means backward arrows, 2 is for forward arrows and 3 for both. If it is a character vector then “<” and “<-” specify backward, “>” and “->” forward arrows and “<>” and “<->” stands for both arrows. All other values mean no arrows, perhaps you should use “-” or “–” to specify no arrows.

Hint: this parameter can be used as a ‘cheap’ solution for drawing “mixed” graphs: graphs in which some edges are directed some are not. If you want do this, then please create a directed graph, because as of version 0.4 the vertex pairs in the edge lists can be swapped in undirected graphs.

By default, no arrows will be drawn for undirected graphs, and for directed graphs, an arrow will be drawn for each edge, according to its direction. This is not very surprising, it is the expected behavior.
**loop.angle**  Gives the angle in radian for plotting loop edges. See the `label.dist` vertex parameter to see how this is interpreted.

The default value is 0.

**loop.angle2**  Gives the second angle in radian for plotting loop edges. This is only used in 3D, `loop.angle` is enough in 2D.

The default value is 0.

Other parameters:

**layout**  Either a function or a numeric matrix. It specifies how the vertices will be placed on the plot.

If it is a numeric matrix, then the matrix has to have one line for each vertex, specifying its coordinates. The matrix should have at least two columns, for the x and y coordinates, and it can also have third column, this will be the z coordinate for 3D plots and it is ignored for 2D plots.

If a two column matrix is given for the 3D plotting function `rglplot` then the third column is assumed to be 1 for each vertex.

If `layout` is a function, this function will be called with the graph as the single parameter to determine the actual coordinates. The function should return a matrix with two or three columns. For the 2D plots the third column is ignored.

The default value is `layout.random`, i.e. a function returning with 2D random placement.

**margin**  The amount of empty space below, over, at the left and right of the plot, it is a numeric vector of length four. Usually values between 0 and 0.5 are meaningful, but negative values are also possible, that will make the plot zoom in to a part of the graph. If it is shorter than four then it is recycled.

`rglplot` does not support this parameter, as it can zoom in and out the graph in a more flexible way.

Its default value is 0.

**rescale**  Logical constant, whether to rescale the coordinates to the [-1,1]x[-1,1](x[-1,1]) interval. This parameter is not implemented for `tkplot`.

Defaults to `TRUE`, the layout will be rescaled.

**asp**  A numeric constant, it gives the `asp` parameter for `plot`, the aspect ratio. Supply 0 here if you don’t want to give an aspect ratio. It is ignored by `tkplot` and `rglplot`.

Defaults to 1.

**frame**  Boolean, whether to plot a frame around the graph. It is ignored by `tkplot` and `rglplot`.

Defaults to `FALSE`.

**main**  Overall title for the main plot. The default is empty if the `annotate.plot` igraph option is `FALSE`, and the graph’s name attribute otherwise. See the same argument of the base `plot` function. Only supported by `plot`.

**sub**  Subtitle of the main plot, the default is empty. Only supported by `plot`.

**xlab**  Title for the x axis, the default is empty if the `annotate.plot` igraph option is `FALSE`, and the number of vertices and edges, if it is `TRUE`. Only supported by `plot`.

**ylab**  Title for the y axis, the default is empty. Only supported by `plot`.

## End(Not run)
dyad.census

Dyad census of a graph

Description

Classify dyads in a directed graphs. The relationship between each pair of vertices is measured. It can be in three states: mutual, asymmetric or non-existent.

Usage

dyad.census(graph)

Arguments

- graph: The input graph. A warning is given if it is not directed.

Value

A named numeric vector with three elements:

- mut: The number of pairs with mutual connections.
- asym: The number of pairs with non-mutual connections.
- null: The number of pairs with no connection between them.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

References

See Also

- **triad.census** for the same classification, but with triples.

Examples

```r
  g <- ba.game(100)
  dyad.census(g)
```
eccentricity

Eccentricity and radius

Description

The eccentricity of a vertex is its shortest path distance from the farthest other node in the graph. The smallest eccentricity in a graph is called its radius.

Usage

eccentricity(graph, vids=V(graph), mode=c("all", "out", "in", "total"))
radius(graph, mode=c("all", "out", "in", "total"))

Arguments

- **graph**: The input graph, it can be directed or undirected.
- **vids**: The vertices for which the eccentricity is calculated.
- **mode**: Character constant, gives whether the shortest paths to or from the given vertices should be calculated for directed graphs. If "out" then the shortest paths from the vertex, if "in" then to it will be considered. If "all", the default, then the corresponding undirected graph will be used, edge directions will be ignored. This argument is ignored for undirected graphs.

Details

The eccentricity of a vertex is calculated by measuring the shortest distance from (or to) the vertex, to (or from) all vertices in the graph, and taking the maximum.

This implementation ignores vertex pairs that are in different components. Isolate vertices have eccentricity zero.

Value

eccentricity returns a numeric vector, containing the eccentricity score of each given vertex.
radius returns a numeric scalar.

shortest.paths for general shortest path calculations.
edge.betweenness.community

Community structure detection based on edge betweenness

Description

Many networks consist of modules which are densely connected themselves but sparsely connected to other modules.

Usage

edge.betweenness.community (graph, weights = E(graph)$weight, directed = TRUE, edge.betweenness = TRUE, merges = TRUE, bridges = TRUE, modularity = TRUE, membership = TRUE)

Arguments

graph The graph to analyze.
weights The edge weights. Supply NULL to omit edge weights. By default the ‘weight’ edge attribute is used, if it is present.
directed Logical constant, whether to calculate directed edge betweenness for directed graphs. It is ignored for undirected graphs.
edge.betweenness Logical constant, whether to return the edge betweenness of the edges at the time of their removal.
merges Logical constant, whether to return the merge matrix representing the hierarchical community structure of the network. This argument is called merges, even if the community structure algorithm itself is divisive and not agglomerative: it builds the tree from top to bottom. There is one line for each merge (i.e. split) in matrix, the first line is the first merge (last split). The communities are identified by integer number starting from one. Community ids smaller than or equal to N, the number of vertices in the graph, belong to singleton communities, ie. individual vertices. Before the first merge we have N communities numbered from one to N. The first merge, the first line of the matrix creates community N + 1, the second merge creates community N + 2, etc.
bridges Logical constant, whether to return a list the edge removals which actually split a component of the graph.
modularity Logical constant, whether to calculate the maximum modularity score, considering all possibly community structures along the edge-betweenness based edge removals.
membership Logical constant, whether to calculate the membership vector corresponding to the highest possible modularity score.
Details

The edge betweenness score of an edge measures the number of shortest paths through it, see `edge.betweenness` for details. The idea of the edge betweenness based community structure detection is that it is likely that edges connecting separate modules have high edge betweenness as all the shortest paths from one module to another must traverse through them. So if we gradually remove the edge with the highest edge betweenness score we will get a hierarchical map, a rooted tree, called a dendrogram of the graph. The leafs of the tree are the individual vertices and the root of the tree represents the whole graph.

`edge.betweenness.community` performs this algorithm by calculating the edge betweenness of the graph, removing the edge with the highest edge betweenness score, then recalculating edge betweenness of the edges and again removing the one with the highest score, etc.

`edge.betweenness.community` returns various information collected through the run of the algorithm. See the return value down here.

Value

`edge.betweenness.community` returns a `community` object, please see the `community` manual page for details.

Examples

```r
  g <- barabasi.game(100, m=2)
  eb <- edge.betweenness.community(g)

  g <- graph.full(10) %du% graph.full(10)
  g <- add.edges(g, c(7,11))
  eb <- edge.betweenness.community(g)
  eb
```
edge.connectivity

Description

The edge connectivity of a graph or two vertices, this is recently also called group adhesion.

Usage

edge.connectivity(graph, source=NULL, target=NULL, checks=TRUE)
edge.disjoint.paths(graph, source, target)
graph.adhesion(graph, checks=TRUE)

Arguments

graph The input graph.
source The id of the source vertex, for edge.connectivity it can be NULL, see details below.
target The id of the target vertex, for edge.connectivity it can be NULL, see details below.
checks Logical constant. Whether to check that the graph is connected and also the degree of the vertices. If the graph is not (strongly) connected then the connectivity is obviously zero. Otherwise if the minimum degree is one then the edge connectivity is also one. It is a good idea to perform these checks, as they can be done quickly compared to the connectivity calculation itself. They were suggested by Peter McMahan, thanks Peter.

Details

The edge connectivity of a pair of vertices (source and target) is the minimum number of edges needed to remove to eliminate all (directed) paths from source to target. edge.connectivity calculates this quantity if both the source and target arguments are given (and not NULL).

The edge connectivity of a graph is the minimum of the edge connectivity of every (ordered) pair of vertices in the graph. edge.connectivity calculates this quantity if neither the source nor the target arguments are given (ie. they are both NULL).

A set of edge disjoint paths between two vertices is a set of paths between them containing no common edges. The maximum number of edge disjoint paths between two vertices is the same as their edge connectivity.

The adhesion of a graph is the minimum number of edges needed to remove to obtain a graph which is not strongly connected. This is the same as the edge connectivity of the graph.

The three functions documented on this page calculate similar properties, more precisely the most general is edge.connectivity, the others are included only for having more descriptive function names.
Value

A scalar real value.

edge.connectivity(g2, 100, 1)
edge.disjoint.paths(g2, 100, 1)

g <- erdos.renyi.game(50, 5/50)
g <- as.directed(g)
g <- induced.subgraph(g, subcomponent(g, 1))
graph.adhesion(g)

erdos.renyi.game Generate random graphs according to the Erdos-Renyi model

Description

This model is very simple, every possible edge is created with the same constant probability.

Usage

erdos.renyi.game(n, p.or.m, type=c("gnp", "gnm"),
directed = FALSE, loops = FALSE, ...)

Arguments

n The number of vertices in the graph.
p.or.m Either the probability for drawing an edge between two arbitrary vertices (G(n,p) graph), or the number of edges in the graph (for G(n,m) graphs).
type The type of the random graph to create, either gnp (G(n,p) graph) or gnm (G(n,m) graph).
evcent

directed Logical, whether the graph will be directed, defaults to FALSE.
direct Logical, whether to add loop edges, defaults to FALSE.
...
Additional arguments, ignored.

Details
In G(n,p) graphs, the graph has ‘n’ vertices and for each edge the probability that it is present in the
graph is ‘p’.
In G(n,m) graphs, the graph has ‘n’ vertices and ‘m’ edges, and the ‘m’ edges are chosen uniformly
randomly from the set of all possible edges. This set includes loop edges as well if the loops
parameter is TRUE.
random.graph.game is an alias to this function.

Value
A graph object.

evcent  

Find Eigenvector Centrality Scores of Network Positions

Description
evcent takes a graph (graph) and returns the eigenvector centralities of positions v within it

Usage

```
evcent (graph, directed = FALSE, scale = TRUE, weights = NULL, options = igraph.arpack.default)
```
Arguments

- **graph**: Graph to be analyzed.
- **directed**: Logical scalar, whether to consider direction of the edges in directed graphs. It is ignored for undirected graphs.
- **scale**: Logical scalar, whether to scale the result to have a maximum score of one. If no scaling is used then the result vector has unit length in the Euclidean norm.
- **weights**: A numerical vector or NULL. This argument can be used to give edge weights for calculating the weighted eigenvector centralities of vertices. If this is NULL and the graph has a weight edge attribute then that is used. If weights is a numerical vector then it is used, even if the graph has a weights edge attribute. If this is NA then no edge weights are used (even if the graph has a weight edge attribute). Note that if there are negative edge weights and the direction of the edges is considered, then the eigenvector might be complex. In this case only the real part is reported.
- **options**: A named list, to override some ARPACK options. See `arpack` for details.

Details

Eigenvector centrality scores correspond to the values of the first eigenvector of the graph adjacency matrix; these scores may, in turn, be interpreted as arising from a reciprocal process in which the centrality of each actor is proportional to the sum of the centralities of those actors to whom he or she is connected. In general, vertices with high eigenvector centralities are those which are connected to many other vertices which are, in turn, connected to many others (and so on). (The perceptive may realize that this implies that the largest values will be obtained by individuals in large cliques (or high-density substructures). This is also intelligible from an algebraic point of view, with the first eigenvector being closely related to the best rank-1 approximation of the adjacency matrix (a relationship which is easy to see in the special case of a diagonalizable symmetric real matrix via the $SLS^{-1}$ decomposition).

From igraph version 0.5 this function uses ARPACK for the underlying computation, see `arpack` for more about ARPACK in igraph.

Value

A named list with components:

- **vector**: A vector containing the centrality scores.
- **value**: The eigenvalue corresponding to the calculated eigenvector, i.e. the centrality scores.
- **options**: A named list, information about the underlying ARPACK computation. See `arpack` for the details.

WARNING

evcnet will not symmetrize your data before extracting eigenvectors; don’t send this routine asymmetric matrices unless you really mean to do so.
fastgreedy.community

Description

This function tries to find dense subgraph, also called communities in graphs via directly optimizing a modularity score.

Usage

fastgreedy.community(graph, merges=TRUE, modularity=TRUE, membership=TRUE, weights=E(graph)$weight)

Arguments

graph The input graph
merges Logical scalar, whether to return the merge matrix.
modularity Logical scalar, whether to return a vector containing the modularity after each merge.
membership Logical scalar, whether to calculate the membership vector corresponding to the maximum modularity score, considering all possible community structures along the merges.
weights If not NULL, then a numeric vector of edge weights. The length must match the number of edges in the graph. By default the ‘weight’ edge attribute is used as weights. If it is not present, then all edges are considered to have the same weight.

Details

Value

fastgreedy.community returns a communities object, please see the communities manual page for details.

Examples

g <- graph.full(5) %du% graph.full(5) %du% graph.full(5)
g <- add.edges(g, c(1, 6, 1, 11, 6, 11))
fc <- fastgreedy.community(g)
membership(fc)
sizes(fc)

Description

This is a growing network model, which resembles of how the forest fire spreads by igniting trees close by.

Usage

forest.fire.game (nodes, fw.prob, bw.factor = 1, ambs = 1, directed = TRUE)

Arguments

nodes The number of vertices in the graph.
fw.prob The forward burning probability, see details below.
bw.factor The backward burning ratio. The backward burning probability is calculated as bw.factor=fw.prob.
ambs The number of ambassador vertices.
directed Logical scalar, whether to create a directed graph.
Details

The forest fire model intends to reproduce the following network characteristics, observed in real networks:

- Heavy-tailed in-degree distribution.
- Heavy-tailed out-degree distribution.
- Communities.
- Densification power-law. The network is densifying in time, according to a power-law rule.
- Shrinking diameter. The diameter of the network decreases in time.

The network is generated in the following way. One vertex is added at a time. This vertex connects to (cites) \textit{amb} vertices already present in the network, chosen uniformly random. Now, for each cited vertex \( v \) we do the following procedure:

1. We generate two random number, \( x \) and \( y \), that are geometrically distributed with means \( p/(1-p) \) and \( rp(1-rp) \). (\( p \) is \texttt{prob}, \( r \) is \texttt{factor}.) The new vertex cites \( x \) outgoing neighbors and \( y \) incoming neighbors of \( v \), from those which are not yet cited by the new vertex. If there are less than \( x \) or \( y \) such vertices available then we cite all of them.

2. The same procedure is applied to all the newly cited vertices.

Value

A simple graph, possibly directed if the \texttt{directed} argument is \texttt{true}.

Note

The version of the model in the published paper is incorrect in the sense that it cannot generate the kind of graphs the authors claim. A corrected version is available from \url{http://www.cs.cmu.edu/~jure/pubs/powergrowth-tkdd.pdf}, our implementation is based on this.

\texttt{barabasi.game} for the basic preferential attachment model.
get.adjlist

Adjacency lists

Description
Create adjacency lists from a graph, either for adjacent edges or for neighboring vertices.

Usage
get.adjlist(graph, mode = c("all", "out", "in", "total"))
get.edgedgelist(graph, mode = c("all", "out", "in", "total"))

Arguments
graph The input graph.
mode Character scalar, it gives what kind of adjacent edges/vertices to include in the lists. 'out' is for outgoing edges/vertices, 'in' is for incoming edges/vertices, 'all' is for both. This argument is ignored for undirected graphs.

Details
get.adjlist returns a list of numeric vectors, which include the ids of neighbor vertices (according to the mode argument) of all vertices.
get.edgedgelist returns a list of numeric vectors, which include the ids of adjacent edges (according to the mode argument) of all vertices.

Value
A list of numeric vectors.

Author(s)
Gabor Csardi <csardi.gabor@gmail.com>

Examples

```r
g <- graph.ring(10)
get.adjlist(g)
get.edgedgelist(g)
```

---

### Description

Find the edges in an igraph graph that have the specified end points. This function handles multigraph (graphs with multiple edges) and can consider or ignore the edge directions in directed graphs.

### Usage

```r
get.edge.ids(graph, vp, directed = TRUE, error = FALSE, multi = FALSE)
```

### Arguments

- **graph**: The input graph.
- **vp**: The incident vertices, given as vertex ids or symbolic vertex names. They are interpreted pairwise, i.e. the first and second are used for the first edge, the third and fourth for the second, etc.
- **directed**: Logical scalar, whether to consider edge directions in directed graphs. This argument is ignored for undirected graphs.
- **error**: Logical scalar, whether to report an error if an edge is not found in the graph. If FALSE, then no error is reported, and zero is returned for the non-existant edge(s).
- **multi**: Logical scalar, whether to handle multiple edges properly. If TRUE, a pair of vertices are given twice (or more), then always the same edge id is reported back for them. If TRUE, then the edge ids of multiple edges are correctly reported.

### Details

igraph vertex ids are natural numbers, starting from one, up to the number of vertices in the graph. Similarly, edges are also numbered from one, up to the number of edges.

This function allows finding the edges of the graph, via their incident vertices.

### Value

A numeric vector of edge ids, one for each pair of input vertices. If there is no edge in the input graph for a given pair of vertices, then zero is reported. (If the error argument is FALSE.)

### Author(s)

Gabor Csardi <csardi.gabor@gmail.com>
get.incidence

Examples

g <- graph.ring(10)
ei <- get.edge.ids(g, c(1,2, 4,5))
E(g)[ei]

## non-existent edge
g.get.edge.ids(g, c(2,1, 1,4, 5,4))

---

get.incidence

Incidence matrix of a bipartite graph

Description

This function can return a sparse or dense incidence matrix of a bipartite network. The incidence matrix is an \( n \) times \( m \) matrix, \( n \) and \( m \) are the number of vertices of the two kinds.

Usage

get.incidence(graph, types=NULL, attr=NULL, names=TRUE, sparse=FALSE)

Arguments

graph

The input graph. The direction of the edges is ignored in directed graphs.

types

An optional vertex type vector to use instead of the type vertex attribute. You must supply this argument if the graph has no type vertex attribute.

attr

Either NULL or a character string giving an edge attribute name. If NULL, then a traditional incidence matrix is returned. If not NULL then the values of the given edge attribute are included in the incidence matrix. If the graph has multiple edges, the edge attribute of an arbitrarily chosen edge (for the multiple edges) is included.

names

Logical scalar, if TRUE and the vertices in the graph are named (i.e. the graph has a vertex attribute called name), then vertex names will be added to the result as row and column names. Otherwise the ids of the vertices are used as row and column names.

sparse

Logical scalar, if it is TRUE then a sparse matrix is created, you will need the Matrix package for this.

Details

Bipartite graphs have a type vertex attribute in igraph, this is boolean and FALSE for the vertices of the first kind and TRUE for vertices of the second kind.

Value

A sparse or dense matrix.
get.stochastic

Description

Retrieves the stochastic matrix of a graph of class igraph.

Usage

get.stochastic(graph, column.wise = FALSE, sparse = getIgraphOpt("sparsematrices"))

Arguments

graph The input graph. Must be of class igraph.
column.wise If FALSE, then the rows of the stochastic matrix sum up to one; otherwise it is the columns.
sparse Logical scalar, whether to return a sparse matrix. The Matrix package is needed for sparse matrices.

Details

Let \( M \) be an \( n \times n \) adjacency matrix with real non-negative entries. Let us define \( D = \text{diag}(\sum_i M_{1i}, \ldots, \sum_i M_{ni}) \). The (row) stochastic matrix is defined as

\[
W = D^{-1} M,
\]

where it is assumed that \( D \) is non-singular. Column stochastic matrices are defined in a symmetric way.

Value

A regular \texttt{R} matrix or a matrix of class \texttt{Matrix} if a sparse argument was \texttt{TRUE}.
Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

get.adjacency

Examples

library(Matrix)
## g is a large sparse graph
g <- barabasi.game(n = 10^5, power = 2, directed = FALSE)
W <- get.stochastic(g, sparse=TRUE)

## a dense matrix here would probably not fit in the memory
class(W)

## may not be exactly 1, due to numerical errors
max(abs(rowSums(W))-1)

---

**girth**  
*Girth of a graph*

Description

The girth of a graph is the length of the shortest circle in it.

Usage

`girth(graph, circle=TRUE)`

Arguments

- `graph` The input graph. It may be directed, but the algorithm searches for undirected circles anyway.
- `circle` Logical scalar, whether to return the shortest circle itself.

Details

The current implementation works for undirected graphs only, directed graphs are treated as undirected graphs. Loop edges and multiple edges are ignored. If the graph is a forest (i.e. acyclic), then zero is returned.

This implementation is based on Alon Itai and Michael Rodeh: Finding a minimum circuit in a graph *Proceedings of the ninth annual ACM symposium on Theory of computing*, 1-10, 1977. The first implementation of this function was done by Keith Briggs, thanks Keith.
Value

A named list with two components:

- **girth**: Integer constant, the girth of the graph, or 0 if the graph is acyclic.
- **circle**: Numeric vector with the vertex ids in the shortest circle.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

References

Examples

```r
# No circle in a tree
g <- graph.tree(1000, 3)
girth(g)

# The worst case running time is for a ring
g <- graph.ring(100)
girth(g)

# What about a random graph?
g <- erdos.renyi.game(1000, 1/1000)
girth(g)
```

Description

These functions deal with graph isomorphism.

Usage

```r
graph.isomorphic(graph1, graph2)
graph.isomorphic.34(graph1, graph2)
graph.isomorphic.bliss(graph1, graph2, sh1="fm", sh2="fm")
graph.isomorphic.vf2(graph1, graph2, vertex.color1, vertex.color2, edge.color1, edge.color2)

graph.count.isomorphisms.vf2(graph1, graph2, vertex.color1, vertex.color2, edge.color1, edge.color2)
graph.get.isomorphisms.vf2(graph1, graph2,
```

```r
```
vertex.color1, vertex.color2,
edge.color1, edge.color2)

graph.subisomorphic.vf2(graph1, graph2,
vertex.color1, vertex.color2,
edge.color1, edge.color2)

graph.count.subisomorphisms.vf2(graph1, graph2,
vertex.color1, vertex.color2,
edge.color1, edge.color2)

graph.get.subisomorphisms.vf2(graph1, graph2,
vertex.color1, vertex.color2,
edge.color1, edge.color2)

graph.subisomorphic.lad (pattern, target, domains = NULL,
induced = FALSE, map = TRUE, all.maps = FALSE,
time.limit = Inf)

graph.isoclass(graph)
graph.isoclass.subgraph(graph, vids)
graph.isocreate(size, number, directed=TRUE)

Arguments

graph A graph object.

graph1, graph2 Graph objects
vertex.color1, vertex.color2
Optional integer vectors giving the colors of the vertices for colored (sub)graph
isomorphism. If they are not given, but the graph has a “color” vertex attribute,
then it will be used. If you want to ignore these attributes, then supply NULL for
both of these arguments. See also examples below.

edge.color1, edge.color2
Optional integer vectors giving the colors of the edges for edge-colored (sub)graph
isomorphism. If they are not given, but the graph has a “color” edge attribute,
then it will be used. If you want to ignore these attributes, then supply NULL for
both of these arguments.

size A numeric integer giving the number of vertices in the graph to create. Only
three or four are supported right now.

number The number of the isomorphism class of the graph to be created.
directed Whether to create a directed graph.

sh1 Character constant, the heuristics to use in the BLISS algorithm, for graph1.
See the sh argument of canonical.permutation for possible values.

sh2 Character constant, the heuristics to use in the BLISS algorithm, for graph2.
See the sh argument of canonical.permutation for possible values.

vids Numeric vector, the vertex ids of vertices to form the induced subgraph for de-
terning the isomorphism class.

pattern The smaller graph, it might be directed or undirected. Undirected graphs are
treated as directed graphs with mutual edges.
target The bigger graph, it might be directed or undirected. Undirected graphs are treated as directed graphs with mutual edges.

domains If not NULL, then it specifies matching restrictions. It must be a list of target vertex sets, given as numeric vertex ids or symbolic vertex names. The length of the list must be vcount(pattern) and for each vertex in pattern it gives the allowed matching vertices in target.

induced Logical scalar, whether to search for an induced subgraph. It is FALSE by default.

map Logical scalar, whether to return a mapping between pattern and target. Defaults to TRUE.

all.maps Logical scalar, whether to return all mappings between pattern and target. Defaults to FALSE.

time.limit The processor time limit for the computation, in seconds. It defaults to Inf, which means no limit.

Details

graph.isomorphic decides whether two graphs are isomorphic. The input graphs must be both directed or both undirected. This function is a higher level interface to the other graph isomorphism decision functions. Currently it does the following:

1. If the two graphs do not agree in the number of vertices and the number of edges then FALSE is returned.
2. Otherwise if the graphs have 3 or 4 vertices, then igraph.isomorphic.34 is called.
3. Otherwise if the graphs are directed, then igraph.isomorphic.vf2 is called.
4. Otherwise igraph.isomorphic.bliss is called.

igraph.isomorphic.34 decides whether two graphs, both of which contains only 3 or 4 vertices, are isomorphic. It works based on a precalculated and stored table.

igraph.isomorphic.bliss uses the BLISS algorithm by Junttila and Kaski, and it works for undirected graphs. For both graphs the canonical.permutation and then the permute.vertices function is called to transfer them into canonical form; finally the canonical forms are compared.

igraph.isomorphic.vf2 decides whether two graphs are isomorphic, it implements the VF2 algorithm, by Cordella, Foggia et al., see references.

graph.count.isomorphisms.vf2 counts the different isomorphic mappings between graph1 and graph2. (To count automorphisms you can supply the same graph twice, but it is better to call graph.automorphisms.) It uses the VF2 algorithm.

graph.get.isomorphisms.vf2 calculates all isomorphic mappings between graph1 and graph2. It uses the VF2 algorithm.

graph.subisomorphic.vf2 decides whether graph2 is isomorphic to some subgraph of graph1. It uses the VF2 algorithm.

graph.count.subisomorphisms.vf2 counts the different isomorphic mappings between graph2 and the subgraphs of graph1. It uses the VF2 algorithm.

graph.get.subisomorphisms.vf2 calculates all isomorphic mappings between graph2 and the subgraphs of graph1. It uses the VF2 algorithm.
graph.isomorphic(T1, T2) checks whether pattern is isomorphic to a subgraph or induced subgraph of target. It can also optionally return a mapping, or all possible mappings between the two graphs. Its domains argument allows for a flexible way to restrict the matching to a subset of allowed vertices, individually for each vertex in pattern.

graph.isoclass returns the isomorphism class of a graph, a non-negative integer number. Graphs (with the same number of vertices) having the same isomorphism class are isomorphic and isomorphic graphs always have the same isomorphism class. Currently it can handle only graphs with 3 or 4 vertices.

graph.isoclass.subgraph calculates the isomorphism class of a subgraph of the input graph. Currently it only works for subgraphs with 3 or 4 vertices.

graph.isocreate create a graph from the given isomorphic class. Currently it can handle only graphs with 3 or 4 vertices.

Value

graph.isomorphic and graph.isomorphic.34 return a logical scalar, TRUE if the input graphs are isomorphic, FALSE otherwise.

graph.isomorphic.bliss returns a named list with elements:

iso A logical scalar, whether the two graphs are isomorphic.

map12 A numeric vector, an mapping from graph1 to graph2 if iso is TRUE, an empty numeric vector otherwise.

map21 A numeric vector, an mapping from graph2 to graph1 if iso is TRUE, an empty numeric vector otherwise.

info1 Some information about the canonical form calculation for graph1. A named list, see the return value of canonical.permutation for details. Note that if the two graphs have different number of vertices or edges, then the BLISS algorithm is not run at all, and the contents of info1 is incorrect.

info2 Some information about the canonical form calculation for graph2. A named list, see the return value of canonical.permutation for details. Note that if the two graphs have different number of vertices or edges, then the BLISS algorithm is not run at all, and the contents of info2 is incorrect.

graph.isomorphic.vf2 returns a names list with three elements:

iso A logical scalar, whether the two graphs are isomorphic.

map12 A numeric vector, an mapping from graph1 to graph2 if iso is TRUE, an empty numeric vector otherwise.

map21 A numeric vector, an mapping from graph2 to graph1 if iso is TRUE, an empty numeric vector otherwise.

graph.count.isomorphisms.vf2 returns a numeric scalar, an integer, the number of isomorphic mappings between the two input graphs.

graph.get.isomorphisms.vf2 returns a list of numeric vectors. Every numeric vector is a permutation which takes graph2 into graph1.

graph.subisomorphic.vf2 returns a named list with three elements:
iso Logical scalar, TRUE if a subgraph of graph1 is isomorphic to graph2.
map12 Numeric vector, empty if iso is FALSE. Otherwise a mapping from a subgraph of graph1 to graph2. -1 denotes the vertices which are not part of the mapping.
map21 Numeric vector, empty if iso is FALSE. Otherwise a mapping from graph2 into graph1.

graph.count.subisomorphisms.vf2 returns a numeric scalar, an integer.
graph.get.subisomorphisms.vf2 returns a list of numeric vectors, each numeric vector is an isomorphic mapping from graph2 to a subgraph of graph1.
graph.subisomorphic.lad return a named list with three entries:
iso Logical scalar, whether the algorithm found a subgraph (or induced subgraph is the induced argument in TRUE) in target that is isomorphic to pattern.
map If a mapping is requested via the map argument, then a numeric vector of vertex ids from target, the matching vertices for each pattern vertex in pattern vertex id order. Otherwise NULL.
maps If all mappings are requested via the all.maps argument, then all possible mappings from pattern to target, in a list of vectors, where each vector is in the same format as map just above.

graph.isoclass and graph.isoclass.subgraph return a non-negative integer number.
graph.isocreate returns a graph object.

Note
Functions graph.isoclass, graph.isoclass.subgraph and graph.isocreate are considered experimental and might be reorganized/rewritten later.

# Directed LAD example
Description

Graph motifs are small connected subgraphs with a well-defined structure. These functions search a graph for various motifs.

Usage

```
graph.motifs(graph, size = 3, cut.prob = rep(0, size))
graph.motifs.no(graph, size = 3, cut.prob = rep(0, size))
graph.motifs.est(graph, size = 3, cut.prob = rep(0, size), sample.size = vcount(graph)/10, sample = NULL)
```

Arguments

- `graph` : Graph object, the input graph.
- `size` : The size of the motif, currently 3 and 4 are supported only.
- `cut.prob` : Numeric vector giving the probabilities that the search graph is cut at a certain level. Its length should be the same as the size of the motif (the size argument). By default no cuts are made.
- `sample.size` : The number of vertices to use as a starting point for finding motifs. Only used if the sample argument is NULL.
- `sample` : If not NULL then it specifies the vertices to use as a starting point for finding motifs.

Details

`graph.motifs` searches a graph for motifs of a given size and returns a numeric vector containing the number of different motifs. The order of the motifs is defined by their isomorphism class, see `graph.isoclass`.

`graph.motifs.no` calculates the total number of motifs of a given size in graph.

`graph.motifs.est` estimates the total number of motifs of a given size in a graph based on a sample.

Value

- `graph.motifs` returns a numeric vector, the number of occurrences of each motif in the graph. The motifs are ordered by their isomorphism classes. Note that for unconnected subgraphs, which are not considered to be motifs, the result will be NA.
- `graph.motifs.no` and `graph.motifs.est` return a numeric constant.

```r
pattern <- graph.formula(1:2:3, 1 -> 2:3)
uring <- graph.ring(10)
dring <- graph.ring(10, directed=TRUE)
graph.subisomorphic.lad(pattern, uring)
graph.subisomorphic.lad(pattern, dring)
```
graph.adjacency

Create graphs from adjacency matrices

Description

graph.adjacency is a flexible function for creating igraph graphs from adjacency matrices.

Usage

graph.adjacency(adjmatrix, mode=c("directed", "undirected", "max", "min", "upper", "lower", "plus"), weighted=NULL, diag=TRUE, add.colnames=NULL, add.rownames=NA)

Arguments

adjmatrix A square adjacency matrix. From igraph version 0.5.1 this can be a sparse matrix created with the Matrix package.

mode Character scalar, specifies how igraph should interpret the supplied matrix. See also the weighted argument, the interpretation depends on that too. Possible values are: directed, undirected, upper, lower, max, min, plus. See details below.

weighted This argument specifies whether to create a weighted graph from an adjacency matrix. If it is NULL then an unweighted graph is created and the elements of the adjacency matrix gives the number of edges between the vertices. If it is a character constant then for every non-zero matrix entry an edge is created and the value of the entry is added as an edge attribute named by the weighted argument. If it is TRUE then a weighted graph is created and the name of the edge attribute will be weight. See also details below.

diag Logical scalar, whether to include the diagonal of the matrix in the calculation. If this is FALSE then the diagonal is zero'd out first.

See Also

graph.isoclass

Examples

g <- barabasi.game(100)
graph.motifs(g, 3)
graph.motifs.no(g, 3)
graph.motifs.est(g, 3)
add.colnames Character scalar, whether to add the column names as vertex attributes. If it is 
'NULL' (the default) then, if present, column names are added as vertex attribute 
'name'. If 'NA' then they will not be added. If a character constant, then it gives 
the name of the vertex attribute to add.

add.rownames Character scalar, whether to add the row names as vertex attributes. Possible 
values the same as the previous argument. By default row names are not added. 
If 'add.rownames' and 'add.colnames' specify the same vertex attribute, then 
the former is ignored.

Details

graph.adjacency creates a graph from an adjacency matrix.

The order of the vertices are preserved, i.e. the vertex corresponding to the first row will be vertex 
0 in the graph, etc.

graph.adjacency operates in two main modes, depending on the weighted argument.

If this argument is NULL then an unweighted graph is created and an element of the adjacency matrix 
gives the number of edges to create between the two corresponding vertices. The details depend on 
the value of the mode argument:

directed The graph will be directed and a matrix element gives the number of edges between two 
vertices.

undirected This is exactly the same as max, for convenience. Note that it is not checked whether 
the matrix is symmetric.

max An undirected graph will be created and max(A(i,j), A(j,i)) gives the number of edges.

upper An undirected graph will be created, only the upper right triangle (including the diagonal) 
is used for the number of edges.

lower An undirected graph will be created, only the lower left triangle (including the diagonal) is 
used for creating the edges.

min undirected graph will be created with min(A(i,j), A(j,i)) edges between vertex i and j.

plus undirected graph will be created with A(i,j)+A(j,i) edges between vertex i and j.

If the weighted argument is not NULL then the elements of the matrix give the weights of the edges 
(if they are not zero). The details depend on the value of the mode argument:

directed The graph will be directed and a matrix element gives the edge weights.

undirected First we check that the matrix is symmetric. It is an error if not. Then only the upper 
triangle is used to create a weighted undirected graph.

max An undirected graph will be created and max(A(i,j), A(j,i)) gives the edge weights.

upper An undirected graph will be created, only the upper right triangle (including the diagonal) 
is used (for the edge weights).

lower An undirected graph will be created, only the lower left triangle (including the diagonal) is 
used for creating the edges.

min An undirected graph will be created, min(A(i,j), A(j,i)) gives the edge weights.

plus An undirected graph will be created, A(i,j)+A(j,i) gives the edge weights.
Value
An igraph graph object.

summary(g10)
```

```
Description

Calculate the number of automorphisms of a graph, i.e. the number of isomorphisms to itself.

Usage

```
graph.automorphisms(graph, sh="fm")
```

Arguments

- **graph**: The input graph, it is treated as undirected.

Details

An automorphism of a graph is a permutation of its vertices which brings the graph into itself.

This function calculates the number of automorphism of a graph using the BLISS algorithm. See also the BLISS homepage at [http://www.tcs.hut.fi/Software/bliss/index.html](http://www.tcs.hut.fi/Software/bliss/index.html).

Value

A named list with the following members:

- **group_size**: The size of the automorphism group of the input graph, as a string. This number is exact if igraph was compiled with the GMP library, and approximate otherwise.
- **nof_nodes**: The number of nodes in the search tree.
- **nof_leaf_nodes**: The number of leaf nodes in the search tree.
- **nof_bad_nodes**: Number of bad nodes.
- **nof_canupdates**: Number of canrep updates.
- **max_level**: Maximum level.

Author(s)

Tommi Juntilla ([http://users.ics.aalto.fi/tjunttil/](http://users.ics.aalto.fi/tjunttil/)) for BLISS and Gabor Csardi <csardi.gabor@gmail.com> for the igraph glue code and this manual page.

canonical.permutation, permute.vertices

Examples

```r
## A ring has n*2 automorphisms, you can "turn" it by 0-9 vertices
## and each of these graphs can be "flipped"

library(ggraph)

g <- graph.ring(10)
graph.automorphisms(g)
```

Description

Breadth-first search is an algorithm to traverse a graph. We start from a root vertex and spread along every edge “simultaneously”.

Usage

```r
graph.bfs (graph, root, neimode = c("out", "in", "all", "total"),
          unreachable = TRUE, restricted = NULL, order = TRUE,
          rank = FALSE, father = FALSE, pred = FALSE, succ = FALSE,
          dist = FALSE, callback = NULL, extra = NULL,
          rho = parent.frame())
```

Arguments

- **graph**: The input graph.
- **root**: Numeric vector, usually of length one. The root vertex, or root vertices to start the search from.
- **neimode**: For directed graphs specifies the type of edges to follow. ‘out’ follows outgoing, ‘in’ incoming edges. ‘all’ ignores edge directions completely. ‘total’ is a synonym for ‘all’. This argument is ignored for undirected graphs.
- **unreachable**: Logical scalar, whether the search should visit the vertices that are unreachable from the given root vertex (or vertices). If TRUE, then additional searches are performed until all vertices are visited.
- **restricted**: NULL (=no restriction), or a vector of vertices (ids or symbolic names). In the latter case, the search is restricted to the given vertices.
- **order**: Logical scalar, whether to return the ordering of the vertices.
**graph.bfs**

- **rank**: Logical scalar, whether to return the rank of the vertices.
- **father**: Logical scalar, whether to return the father of the vertices.
- **pred**: Logical scalar, whether to return the predecessors of the vertices.
- **succ**: Logical scalar, whether to return the successors of the vertices.
- **dist**: Logical scalar, whether to return the distance from the root of the search tree.
- **callback**: If not NULL, then it must be callback function. This is called whenever a vertex is visited. See details below.
- **extra**: Additional argument to supply to the callback function.
- **rho**: The environment in which the callback function is evaluated.

**Details**

The callback function must have the following arguments:

- **graph**: The input graph is passed to the callback function here.
- **data**: A named numeric vector, with the following entries: ‘vid’, the vertex that was just visited, ‘pred’, its predecessor, ‘succ’, its successor, ‘rank’, the rank of the current vertex, ‘dist’, its distance from the root of the search tree.
- **extra**: The extra argument.

See examples below on how to use the callback function.

**Value**

A named list with the following entries:

- **root**: Numeric scalar. The root vertex that was used as the starting point of the search.
- **neimode**: Character scalar. The neimode argument of the function call. Note that for undirected graphs this is always ‘all’, irrespectively of the supplied value.
- **order**: Numeric vector. The vertex ids, in the order in which they were visited by the search.
- **rank**: Numeric vector. The rank for each vertex.
- **father**: Numeric vector. The father of each vertex, i.e. the vertex it was discovered from.
- **pred**: Numeric vector. The previously visited vertex for each vertex, or 0 if there was no such vertex.
- **succ**: Numeric vector. The next vertex that was visited after the current one, or 0 if there was no such vertex.
- **dist**: Numeric vector, for each vertex its distance from the root of the search tree.

Note that order, rank, father, pred, succ and dist might be NULL if their corresponding argument is FALSE, i.e. if their calculation is not requested.

```
graph.bipartite Create a bipartite graph

Description

A bipartite graph has two kinds of vertices and connections are only allowed between different kinds.

Usage

```r
graph.bipartite(types, edges, directed=FALSE)
```

is.bipartite(graph)

Arguments

- **types**: A vector giving the vertex types. It will be coerced into boolean. The length of the vector gives the number of vertices in the graph.
- **edges**: A vector giving the edges of the graph, the same way as for the regular `graph` function. It is checked that the edges indeed connect vertices of different kind, according to the supplied `types` vector.
- **directed**: Whether to create a directed graph, boolean constant. Note that by default undirected graphs are created, as this is more common for bipartite graphs.
- **graph**: The input graph.
Details

Bipartite graphs have a type vertex attribute in igraph, this is boolean and FALSE for the vertices of the first kind and TRUE for vertices of the second kind.

graph.bipartite basically does three things. First it checks the edges vector against the vertex types. Then it creates a graph using the edges vector and finally it adds the types vector as a vertex attribute called type.

is.bipartite checks whether the graph is bipartite or not. It just checks whether the graph has a vertex attribute called type.

Value

graph.bipartite returns a bipartite igraph graph. In other words, an igraph graph that has a vertex attribute named type.

is.bipartite returns a logical scalar.

graph to create one-mode networks

Examples

g <- graph.bipartite( rep(0:1, length=10), c(1:10))
print(g, v=TRUE)

Description

A complementer graph contains all edges that were not present in the input graph.

Usage

graph.complementer(graph, loops=FALSE)

Arguments

graph The input graph, can be directed or undirected.
loops Logical constant, whether to generate loop edges.
Details

`graph.complementer` creates the complementer of a graph. Only edges which are not present in the original graph will be included in the new graph.

`graph.complementer` keeps graph and vertex attributes, edge attributes are lost.

Value

A new graph object.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

Examples

```r
## Complementer of a ring
g <- graph.ring(10)
graph.complementer(g)

## A graph and its complementer give together the full graph
g <- graph.ring(10)
gc <- graph.complementer(g)
gu <- graph.union(g, gc)
gu
graph.isomorphic(gu, graph.full(vcount(g)))
```

---

**graph.compose**  
*Compose two graphs as binary relations*

Description

Relational composition of two graph.

Usage

`graph.compose(g1, g2, byname = "auto")`

Arguments

- `g1` The first input graph.
- `g2` The second input graph.
- `byname` A logical scalar, or the character scalar `auto`. Whether to perform the operation based on symbolic vertex names. If it is `auto`, that means `TRUE` if both graphs are named and `FALSE` otherwise. A warning is generated if `auto` and one graph, but not both graphs are named.
Details

graph.compose creates the relational composition of two graphs. The new graph will contain an 
(a,b) edge only if there is a vertex c, such that edge (a,c) is included in the first graph and (c,b) is 
included in the second graph. The corresponding operator is %c%.

The function gives an error if one of the input graphs is directed and the other is undirected.

If the byname argument is TRUE (or auto and the graphs are all named), then the operation is per-
formed based on symbolic vertex names. Otherwise numeric vertex ids are used.

graph.compose keeps the attributes of both graphs. All graph, vertex and edge attributes are copied 
to the result. If an attribute is present in multiple graphs and would result a name clash, then this 
attribute is renamed by adding suffixes: _1, _2, etc.

The name vertex attribute is treated specially if the operation is performed based on symbolic vertex 
names. In this case name must be present in both graphs, and it is not renamed in the result graph.

Note that an edge in the result graph corresponds to two edges in the input, one in the first graph, 
one in the second. This mapping is not injective and several edges in the result might correspond 
to the same edge in the first (and/or the second) graph. The edge attributes in the result graph are 
updated accordingly.

Also note that the function may generate multigraphs, if there are more than one way to find edges 
(a,b) in g1 and (b,c) in g2 for an edge (a,c) in the result. See simplify if you want to get rid of the 
multiple edges.

The function may create loop edges, if edges (a,b) and (b,a) are present in g1 and g2, respectively, 
then (a,a) is included in the result. See simplify if you want to get rid of the self-loops.

Value

A new graph object.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

Examples

g1 <- graph.ring(10) 
g2 <- graph.star(10, mode="undirected") 
gc <- graph.compose(g1, g2) 
str(gc) 
str(simplify(gc))
Usage

graph.empty(n=0, directed=TRUE)
graph(edges, n=max(edges), directed=TRUE)
graph.star(n, mode=c("in", "out", "mutual", "undirected"), center = 1)
graph.lattice(dimvector = NULL, length = NULL, dim = NULL, nei = 1,
    directed = FALSE, mutual = FALSE, circular = FALSE, ...)
graph.ring(n, directed = FALSE, mutual = FALSE, circular=TRUE)
graph.tree(n, children = 2, mode=c("out", "in", "undirected"))
graph.full(n, directed = FALSE, loops = FALSE)
graph.full.citation(n, directed = TRUE)
graph.atlas(n)
graph.edgelist(el, directed=TRUE)
graph.extended.chordal.ring(n, w)

Arguments

edges Numeric vector defining the edges, the first edge points from the first element to the second, the second edge from the third to the fourth, etc.
directed Logical, if TRUE a directed graph will be created. Note that for while most constructors the default is TRUE, for graph.lattice and graph.ring it is FALSE. For graph.star the mode argument should be used for creating an undirected graph.
n The number of vertices in the graph for most functions. For graph this parameter is ignored if there is a bigger vertex id in edges. This means that for this function it is safe to supply zero here if the vertex with the largest id is not an isolate. For graph.atlas this is the number (id) of the graph to create.
mode For graph.star it defines the direction of the edges, in: the edges point to the center, out: the edges point from the center, mutual: a directed star is created with mutual edges, undirected: the edges are undirected.
For igraph.tree this parameter defines the direction of the edges. out indicates that the edges point from the parent to the children, in indicates that they point from the children to their parents, while undirected creates an undirected graph.
center For graph.star the center vertex of the graph, by default the first vertex.
dimvector A vector giving the size of the lattice in each dimension, for graph.lattice.
nei The distance within which (inclusive) the neighbors on the lattice will be connected. This parameter is not used right now.
mutual Logical, if TRUE directed lattices will be mutually connected.
circular Logical, if TRUE the lattice or ring will be circular.
length Integer constant, for regular lattices, the size of the lattice in each dimension.
dim Integer constant, the dimension of the lattice.
children Integer constant, the number of children of a vertex (except for leafs) for graph.tree.
loops If TRUE also loops edges (self edges) are added.
graph.constructors

- **graph**: An object.
- **el**: An edge list, a two column matrix, character or numeric. See details below.
- **w**: A matrix which specifies the extended chordal ring. See details below.
- **...**: Currently ignored.

**Details**

All these functions create graphs in a deterministic way.

**graph.empty** is the simplest one, this creates an empty graph.

**graph** creates a graph with the given edges.

**graph.star** creates a star graph, in this every single vertex is connected to the center vertex and nobody else.

**graph.lattice** is a flexible function, it can create lattices of arbitrary dimensions, periodic or unperiodic ones. It has two forms. In the first form you only supply `dimvector`, but not `length` and `dim`. In the second form you omit `dimvector` and supply `length` and `dim`.

**graph.ring** is actually a special case of **graph.lattice**, it creates a one dimensional circular lattice.

**graph.tree** creates regular trees.

**graph.full** simply creates full graphs.

**graph.full.citation** creates a full citation graph. This is a directed graph, where every i->j edge is present if and only if j<i. If `directed=FALSE` then the graph is just a full graph.

**graph.atlas** creates graphs from the book An Atlas of Graphs by Roland C. Read and Robin J. Wilson. The atlas contains all undirected graphs with up to seven vertices, numbered from 0 up to 1252. The graphs are listed:

1. in increasing order of number of nodes;
2. for a fixed number of nodes, in increasing order of the number of edges;
3. for fixed numbers of nodes and edges, in increasing order of the degree sequence, for example 111223 < 112222;
4. for fixed degree sequence, in increasing number of automorphisms.

**graph.edgelist** creates a graph from an edge list. Its argument is a two-column matrix, each row defines one edge. If it is a numeric matrix then its elements are interpreted as vertex ids. If it is a character matrix then it is interpreted as symbolic vertex names and a vertex id will be assigned to each name, and also a name vertex attribute will be added.

**graph.extended.chordal.ring** creates an extended chordal ring. An extended chordal ring is regular graph, each node has the same degree. It can be obtained from a simple ring by adding some extra edges specified by a matrix. Let p denote the number of columns in the 'w' matrix. The extra edges of vertex i are added according to column i mod p in 'w'. The number of extra edges is the number of rows in 'w': for each row j an edge i->i+w[ij] is added if i+w[ij] is less than the number of total nodes. See also Kotsis, G: Interconnection Topologies for Parallel Processing Systems, PARS Mitteilungen 11, 1-6, 1993.
Value

Every function documented here returns a graph object.

```

---

**graph.coreness**  
*K-core decomposition of graphs*

Description

The k-core of graph is a maximal subgraph in which each vertex has at least degree k. The coreness of a vertex is k if it belongs to the k-core but not to the (k+1)-core.

Usage

```r
graph.coreness(graph, mode=c("all", "out", "in"))
```

Arguments

- **graph**: The input graph, it can be directed or undirected
- **mode**: The type of the core in directed graphs. Character constant, possible values: in: in-cores are computed, out: out-cores are computed, all: the corresponding undirected graph is considered. This argument is ignored for undirected graphs.
The k-core of a graph is the maximal subgraph in which every vertex has at least degree k. The cores of a graph form layers: the (k+1)-core is always a subgraph of the k-core.

This function calculates the coreness for each vertex.

Value

Numeric vector of integer numbers giving the coreness of each vertex.

degree

Examples

g <- graph.ring(10)
g <- add.edges(g, c(1,2, 2,3, 1,3))
graph.coreness(g)

description

This function creates an igraph graph from one or two data frames containing the (symbolic) edge list and edge/vertex attributes.

Usage

graph.data.frame(d, directed=TRUE, vertices=NULL)
get.data.frame(x, what=c("edges", "vertices", "both"))
Arguments

- **d**: A data frame containing a symbolic edge list in the first two columns. Additional columns are considered as edge attributes. Since version 0.7 this argument is coerced to a data frame with `as.data.frame`.
- **directed**: Logical scalar, whether or not to create a directed graph.
- **vertices**: A data frame with vertex metadata, or `NULL`. See details below. Since version 0.7 this argument is coerced to a data frame with `as.data.frame`, if not `NULL`.
- **x**: An igraph object.
- **what**: Character constant, whether to return info about vertices, edges, or both. The default is ‘edges’.

Details

graph.data.frame creates igraph graphs from one or two data frames. It has two modes of operation, depending whether the vertices argument is `NULL` or not.

If vertices is `NULL`, then the first two columns of `d` are used as a symbolic edge list and additional columns as edge attributes. The names of the attributes are taken from the names of the columns.

If vertices is not `NULL`, then it must be a data frame giving vertex metadata. The first column of vertices is assumed to contain symbolic vertex names, this will be added to the graphs as the ‘name’ vertex attribute. Other columns will be added as additional vertex attributes. If vertices is not `NULL` then the symbolic edge list given in `d` is checked to contain only vertex names listed in vertices.

Typically, the data frames are exported from some spreadsheet software like Excel and are imported into R via `read.table, read.delim` or `read.csv`.

get.data.frame converts the igraph graph into one or more data frames, depending on the what argument.

If the what argument is edges (the default), then the edges of the graph and also the edge attributes are returned. The edges will be in the first two columns, named from and to. (This also denotes edge direction for directed graphs.) For named graphs, the vertex names will be included in these columns, for other graphs, the numeric vertex ids. The edge attributes will be in the other columns. It is not a good idea to have an edge attribute named from or to, because then the column named in the data frame will not be unique. The edges are listed in the order of their numeric ids.

If the what argument is vertices, then vertex attributes are returned. Vertices are listed in the order of their numeric vertex ids.

If the what argument is both, then both vertex and edge data is returned, in a list with named entries vertices and edges.

Value

An igraph graph object for `graph.data.frame`, and either a data frame or a list of two data frames named edges and vertices for `as.data.frame`.
Note

For graph.data.frame NA elements in the first two columns ‘d’ are replaced by the string “NA” before creating the graph. This means that all NAs will correspond to a single vertex.

NA elements in the first column of ‘vertices’ are also replaced by the string “NA”, but the rest of ‘vertices’ is not touched. In other words, vertex names (=the first column) cannot be NA, but other vertex attributes can.

g <- graph.data.frame(relations, directed=TRUE, vertices=actors)
pnt(g, e=TRUE, v=TRUE)

## The opposite operation
get.data.frame(g, what="vertices")
get.data.frame(g, what="edges")
```

Description

De Bruijn graphs are labeled graphs representing the overlap of strings.

Usage

graph.de.bruijn(m,n)
Arguments

- \texttt{m} Integer scalar, the size of the alphabet. See details below.
- \texttt{n} Integer scalar, the length of the labels. See details below.

Details

A de Bruijn graph represents relationships between strings. An alphabet of \( m \) letters are used and strings of length \( n \) are considered. A vertex corresponds to every possible string and there is a directed edge from vertex \( v \) to vertex \( w \) if the string of \( v \) can be transformed into the string of \( w \) by removing its first letter and appending a letter to it.

Please note that the graph will have \( m \) to the power \( n \) vertices and even more edges, so probably you don't want to supply too big numbers for \( m \) and \( n \).

De Bruijn graphs have some interesting properties, please see another source, eg. Wikipedia for details.

Value

A graph object.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

See Also

\texttt{graph.kautz, line.graph}

Examples

```r
# de Bruijn graphs can be created recursively by line graphs as well
g <- graph.de.bruijn(2,1)
graph.de.bruijn(2,2)
line.graph(g)
```

\begin{verbatim}
graph.density  Graph density
\end{verbatim}

Description

The density of a graph is the ratio of the number of edges and the number of possible edges.

Usage

\texttt{graph.density(graph, loops=FALSE)}
graph.density

Arguments

- graph: The input graph.
- loops: Logical constant, whether to allow loop edges in the graph. If this is TRUE then self loops are considered to be possible. If this is FALSE then we assume that the graph does not contain any loop edges and that loop edges are not meaningful.

Details

Note that this function may return strange results for graph with multiple edges, density is ill-defined for graphs with multiple edges.

Value

A real constant. This function returns NaN (=0.0/0.0) for an empty graph with zero vertices.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

References

vcount, ecount, simplify to get rid of the multiple and/or loop edges.

Examples

```r
library(ggraph)

# create a graph with loop edges

# graph with no loops

# graph with loop edges

g <- graph(c(1,2, 2,2, 2,3))

# graph density with loops

# graph density without loops

graph.density(g, loops=FALSE) # this is wrong!!!
graph.density(g, loops=TRUE) # this is right!!!
graph.density(simplify(g), loops=FALSE) # this is also right, but different
```
Depth-first search

Depth-first search is an algorithm to traverse a graph. It starts from a root vertex and tries to go quickly as far from as possible.

Usage

```
graph.dfs (graph, root, neimode = c("out", "in", "all", "total"),
          unreachable = TRUE, order = TRUE, order.out = FALSE,
          father = FALSE, dist = FALSE, in.callback = NULL,
          out.callback = NULL, extra = NULL, rho = parent.frame())
```

Arguments

- `graph`: The input graph.
- `root`: The single root vertex to start the search from.
- `neimode`: For directed graphs specifies the type of edges to follow. 'out' follows outgoing, 'in' incoming edges. 'all' ignores edge directions completely. 'total' is a synonym for 'all'. This argument is ignored for undirected graphs.
- `unreachable`: Logical scalar, whether the search should visit the vertices that are unreachable from the given root vertex (or vertices). If TRUE, then additional searches are performed until all vertices are visited.
- `order`: Logical scalar, whether to return the DFS ordering of the vertices.
- `order.out`: Logical scalar, whether to return the ordering based on leaving the subtree of the vertex.
- `father`: Logical scalar, whether to return the father of the vertices.
- `dist`: Logical scalar, whether to return the distance from the root of the search tree.
- `in.callback`: If not NULL, then it must be callback function. This is called whenever a vertex is visited. See details below.
- `out.callback`: If not NULL, then it must be callback function. This is called whenever the subtree of a vertex is completed by the algorithm. See details below.
- `extra`: Additional argument to supply to the callback function.
- `rho`: The environment in which the callback function is evaluated.

Details

The callback functions must have the following arguments:

- `graph`: The input graph is passed to the callback function here.
- `data`: A named numeric vector, with the following entries: 'vid', the vertex that was just visited and 'dist', its distance from the root of the search tree.
**extra**  The extra argument.

See examples below on how to use the callback functions.

**Value**

A named list with the following entries:

- **root**: Numeric scalar. The root vertex that was used as the starting point of the search.
- **neimode**: Character scalar. The `neimode` argument of the function call. Note that for undirected graphs this is always `all`, irrespectively of the supplied value.
- **order**: Numeric vector. The vertex ids, in the order in which they were visited by the search.
- **order.out**: Numeric vector, the vertex ids, in the order of the completion of their subtree.
- **father**: Numeric vector. The father of each vertex, i.e. the vertex it was discovered from.
- **dist**: Numeric vector, for each vertex its distance from the root of the search tree.

Note that `order`, `order.out`, `father`, and `dist` might be `NULL` if their corresponding argument is `FALSE`, i.e. if their calculation is not requested.

**Author(s)**

Gabor Csardi <csardi.gabor@gmail.com>

**See Also**

`graph.bfs` for breadth-first search.

**Examples**

```r
## A graph with two separate trees
graph.dfs(graph.tree(10) %du% graph.tree(10), root=1, "out", 
          TRUE, TRUE, TRUE, TRUE)

## How to use a callback
f.in <- function(graph, data, extra) {
  cat("in:", paste(collapse=" ", data), "\n")
  FALSE
}
f.out <- function(graph, data, extra) {
  cat("out:", paste(collapse=" ", data), "\n")
  FALSE
}
tmp <- graph.dfs(graph.tree(10), root=1, "out", 
in.callback=f.in, out.callback=f.out)

## Terminate after the first component, using a callback
f.out <- function(graph, data, extra) {
  data['vid'] == 1
}
tmp <- graph.dfs(graph.tree(10) %du% graph.tree(10), root=1,
```
graph.difference

Description

The difference of two graphs are created.

Usage

graph.difference(big, small, byname = "auto")

Arguments

big The left hand side argument of the minus operator. A directed or undirected graph.
small The right hand side argument of the minus operator. A directed or undirected graph.
bname A logical scalar, or the character scalar "auto". Whether to perform the operation based on symbolic vertex names. If it is auto, that means TRUE if both graphs are named and FALSE otherwise. A warning is generated if auto and one graph, but not both graphs are named.

Details

graph.difference creates the difference of two graphs. Only edges present in the first graph but not in the second will be included in the new graph. The corresponding operator is %m%.

If the byname argument is TRUE (or auto and the graphs are all named), then the operation is performed based on symbolic vertex names. Otherwise numeric vertex ids are used.

graph.difference keeps all attributes (graph, vertex and edge) of the first graph.

Note that big and small must both be directed or both be undirected, otherwise an error message is given.

Value

A new graph object.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>
# Examples

```r
## Create a wheel graph
wheel <- graph.union(graph.ring(10),
                      graph.star(11, center=11, mode="undirected"))
V(wheel)$name <- letters[seq_len(vcount(wheel))]

## Subtract a star graph from it
sstar <- graph.star(6, center=6, mode="undirected")
V(sstar)$name <- letters[c(1,3,5,7,9,11)]
G <- wheel %du% sstar
str(G)
plot(G, layout=layout.auto(wheel))
```

---

**graph.disjoint.union**  
*Disjoint union of graphs*

## Description

The union of two or more graphs are created. The graphs are assumed to have disjoint vertex sets.

## Usage

`graph.disjoint.union(...)`

## Arguments

`...`  
Graph objects or lists of graph objects.

## Details

`graph.disjoint.union` creates a union of two or more disjoint graphs. Thus first the vertices in the second, third, etc. graphs are relabeled to have completely disjoint graphs. Then a simple union is created. This function can also be used via the `%du%` operator.

`graph.disjoint.union` handles graph, vertex and edge attributes. In particular, it merges vertex and edge attributes using the basic `c()` function. For graphs that lack some vertex/edge attribute, the corresponding values in the new graph are set to `NA`. Graph attributes are simply copied to the result. If this would result a name clash, then they are renamed by adding suffixes: `_1`, `_2`, etc.

Note that if both graphs have vertex names (i.e. a name vertex attribute), then the concatenated vertex names might be non-unique in the result. A warning is given if this happens.

An error is generated if some input graphs are directed and others are undirected.

## Value

A new graph object.

## Author(s)

Gabor Csardi [csardi.gabor@gmail.com]
graph.diversity

Examples

```r
## A star and a ring
g1 <- graph.star(10, mode="undirected")
V(g1)$name <- letters[1:10]
g2 <- graph.ring(10)
V(g2)$name <- letters[11:20]
str(g1 %du% g2)
```

description

Calculates a measure of diversity for all vertices.

Usage

```r
graph.diversity(graph, weights = NULL, vids = V(graph))
```

Arguments

- `graph`: The input graph. Edge directions are ignored.
- `weights`: NULL, or the vector of edge weights to use for the computation. If NULL, then the ‘weight’ attribute is used. Note that this measure is not defined for unweighted graphs.
- `vids`: The vertex ids for which to calculate the measure.

Details

The diversity of a vertex is defined as the (scaled) Shannon entropy of the weights of its incident edges:

\[ D(i) = \frac{H(i)}{\log k_i} \]

and

\[ H(i) = - \sum_{j=1}^{k_i} p_{ij} \log p_{ij}, \]

where

\[ p_{ij} = \frac{w_{ij}}{\sum_{l=1}^{k_i} V_{il}}, \]

and \( k_i \) is the (total) degree of vertex \( i \), \( w_{ij} \) is the weight of the edge(s) between vertices \( i \) and \( j \).

For vertices with degree less than two the function returns NaN.

Value

A numeric vector, its length is the number of vertices.

E(g2)$weight <- runif(ecount(g2))
E(g3)$weight <- runif(ecount(g3))

graph.diversity(g1)
graph.diversity(g2)
graph.diversity(g3)
```

---

**Description**

Calculate selected eigenvalues and eigenvectors of a (supposedly sparse) graph.

**Usage**

```r
graph.eigen (graph, algorithm = c("arpack", "auto", "lapack", "comp_auto",
"comp_lapack", "comp_arpack"), which = list(),
options = igraph.arpack.default)
```

**Arguments**

- **graph**  
  The input graph, can be directed or undirected.

- **algorithm**  
  The algorithm to use. Currently only arpack is implemented, which uses the ARPACK solver. See also arpack.

- **which**  
  A list to specify which eigenvalues and eigenvectors to calculate. By default the leading (i.e. largest magnitude) eigenvalue and the corresponding eigenvector is calculated.

- **options**  
  Options for the ARPACK solver. See igraph.arpack.default.
Details

The which argument is a list and it specifies which eigenvalues and corresponding eigenvectors to calculate: There are eight options:

1. Eigenvalues with the largest magnitude. Set pos to LM, and howmany to the number of eigenvalues you want.
2. Eigenvalues with the smallest magnitude. Set pos to SM and howmany to the number of eigenvalues you want.
3. Largest eigenvalues. Set pos to LA and howmany to the number of eigenvalues you want.
4. Smallest eigenvalues. Set pos to SA and howmany to the number of eigenvalues you want.
5. Eigenvalues from both ends of the spectrum. Set pos to BE and howmany to the number of eigenvalues you want. If howmany is odd, then one more eigenvalue is returned from the larger end.
6. Selected eigenvalues. This is not (yet) implemented currently.
7. Eigenvalues in an interval. This is not (yet) implemented.
8. All eigenvalues. This is not implemented yet. The standard eigen function does a better job at this, anyway.

Note that ARPACK might be unstable for graphs with multiple components, e.g. graphs with isolate vertices.

Value

Depends on the algorithm used.

For arpack a list with three entries is returned:

- options: See the return value for arpack for a complete description.
- values: Numeric vector, the eigenvalues.
- vectors: Numeric matrix, with the eigenvectors as columns.

description

Creating named graphs

Description

There are some famous, named graphs, sometimes counterexamples to some conjecture or unique graphs with given features. These can be created with this function

Usage

graph.famous(name)

Arguments

name

Character constant giving the name of the graph. It is case insensitive.

Details

graph.famous knows the following graphs:

- **Bull** The bull graph, 5 vertices, 5 edges, resembles to the head of a bull if drawn properly.
- **Chvatal** This is the smallest triangle-free graph that is both 4-chromatic and 4-regular. According to the Grunbaum conjecture there exists an m-regular, m-chromatic graph with n vertices for every m>1 and n>2. The Chvatal graph is an example for m=4 and n=12. It has 24 edges.
- **Coxeter** A non-Hamiltonian cubic symmetric graph with 28 vertices and 42 edges.
- **Cubical** The Platonic graph of the cube. A convex regular polyhedron with 8 vertices and 12 edges.
- **Diamond** A graph with 4 vertices and 5 edges, resembles to a schematic diamond if drawn properly.
- **Dodecahedral, Dodecahedron** Another Platonic solid with 20 vertices and 30 edges.
- **Folkman** The semisymmetric graph with minimum number of vertices, 20 and 40 edges. A semisymmetric graph is regular, edge transitive and not vertex transitive.
- **Franklin** This is a graph whose embedding to the Klein bottle can be colored with six colors, it is a counterexample to the necessity of the Heawood conjecture on a Klein bottle. It has 12 vertices and 18 edges.
- **Frucht** The Frucht Graph is the smallest cubical graph whose automorphism group consists only of the identity element. It has 12 vertices and 18 edges.
- **Grotzsch** The Grötzsch graph is a triangle-free graph with 11 vertices, 20 edges, and chromatic number 4. It is named after German mathematician Herbert Grötzsch, and its existence demonstrates that the assumption of planarity is necessary in Grötzsch’s theorem that every triangle-free planar graph is 3-colorable.
Heawood: The Heawood graph is an undirected graph with 14 vertices and 21 edges. The graph is cubic, and all cycles in the graph have six or more edges. Every smaller cubic graph has shorter cycles, so this graph is the 6-cage, the smallest cubic graph of girth 6.

Herschel: The Herschel graph is the smallest nonhamiltonian polyhedral graph. It is the unique such graph on 11 nodes, and has 18 edges.

House: The house graph is a 5-vertex, 6-edge graph, the schematic draw of a house if drawn properly, basically a triangle of the top of a square.

HouseX: The same as the house graph with an X in the square. 5 vertices and 8 edges.

Icosahedral, Icosahedron: A Platonic solid with 12 vertices and 30 edges.

Levi: The graph is a 4-arc transitive cubic graph, it has 30 vertices and 45 edges.

McGee: The McGee graph is the unique 3-regular 7-cage graph, it has 24 vertices and 36 edges.

Meredith: The Meredith graph is a quartic graph on 70 nodes and 140 edges that is a counterexample to the conjecture that every 4-regular 4-connected graph is Hamiltonian.

Noperfectmatching: A connected graph with 16 vertices and 27 edges containing no perfect matching. A matching in a graph is a set of pairwise non-adjacent edges; that is, no two edges share a common vertex. A perfect matching is a matching which covers all vertices of the graph.

Nonline: A graph whose connected components are the 9 graphs whose presence as a vertex-induced subgraph in a graph makes a nonline graph. It has 50 vertices and 72 edges.

Octahedral, Octahedron: Platonic solid with 6 vertices and 12 edges.

Petersen: A 3-regular graph with 10 vertices and 15 edges. It is the smallest hypohamiltonian graph, i.e. it is non-hamiltonian but removing any single vertex from it makes it Hamiltonian.

Robertson: The unique (4,5)-cage graph, i.e. a 4-regular graph of girth 5. It has 19 vertices and 38 edges.

Smallestcyclicgroup: A smallest nontrivial graph whose automorphism group is cyclic. It has 9 vertices and 15 edges.

Tetrahedral, Tetrahedron: Platonic solid with 4 vertices and 6 edges.

Thomassen: The smallest hypotraceable graph, on 34 vertices and 52 edges. A hypotraceable graph does not contain a Hamiltonian path but after removing any single vertex from it the remainder always contains a Hamiltonian path. A graph containing a Hamiltonian path is called traceable.

Tutte: Tait’s Hamiltonian graph conjecture states that every 3-connected 3-regular planar graph is Hamiltonian. This graph is a counterexample. It has 46 vertices and 69 edges.

Uniquely3colorable: Returns a 12-vertex, triangle-free graph with chromatic number 3 that is uniquely 3-colorable.

Walther: An identity graph with 25 vertices and 31 edges. An identity graph has a single graph automorphism, the trivial one.

Value

A graph object.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

See Also

graph can create arbitrary graphs, see also the other functions on the its manual page for creating special graphs.

Examples

solids <- list(graph.famous("Tetrahedron"),
               graph.famous("Cubical"),
               graph.famous("Octahedron"),
               graph.famous("Dodecahedron"),
               graph.famous("Icosahedron"))
graph.formula()

A simple undirected graph with two vertices called ‘A’ and ‘B’ and one edge only:

graph.formula(A-B)

Remember that the length of the edges does not matter, so we could have written the following, this creates the same graph:

graph.formula( A-----B )

If you have many disconnected components in the graph, separate them with commas. You can also give isolate vertices.

The ‘:’ operator can be used to define vertex sets. If an edge operator connects two vertex sets then every vertex from the first set will be connected to every vertex in the second set. The following form creates a full graph, including loop edges:

graph.formula( A:B:C:D -- A:B:C:D )

In directed graphs, edges will be created only if the edge operator includes a arrow head (‘+’) at the end of the edge:

graph.formula( A -- B -- C )
graph.formula( A -- B -- C )
graph.formula( A -- B -- C )

Thus in the third example no edge is created between vertices B and C. Mutual edges can be also created with a simple edge operator:

graph.formula( A +++ B +++ C ++ D + E)

Note again that the length of the edge operators is arbitrary, ‘+’, ‘++’ and ‘++++++’ have exactly the same meaning.

If the vertex names include spaces or other special characters then you need to quote them:

graph.formula( "this is" ++ "a silly" ++ "graph here" )

You can include any character in the vertex names this way, even ‘+’ and ‘-’ characters. See more examples below.
graph.full.bipartite

Value
A new graph object.

Author(s)
Gabor Csardi <csardi.gabor@gmail.com>

See Also
graph for more general graph creation methods.

Examples

# A simple undirected graph
```r
g <- graph.full.bipartite(Alice-Bob-Cecil-Alice, Daniel-Cecil-Eugene, Cecil-Gordon)
g
```

# Another undirected graph, ":" notation
```r
g2 <- graph.full.bipartite(Alice-Bob:Cecil:Daniel, Cecil:Daniel-Eugene:Gordon)
g2
```

# A directed graph
```r
g3 <- graph.full.bipartite(Alice -- Bob -- Cecil -- Daniel,
                         Eugene -- Gordon:Helen)
g3
```

# A graph with isolate vertices
```r
g4 <- graph.full.bipartite(Alice -- Bob -- Daniel, Cecil:Gordon, Helen)
g4
V(g4)$name
```

# "Arrows" can be arbitrarily long
```r
g5 <- graph.full.bipartite(Alice +--------+ Bob)
g5
```

# Special vertex names
```r
g6 <- graph.full.bipartite("+" -- ":", ":" -- "/", "/" -- "/")
g6
```

Description
Bipartite graphs are also called two-mode by some. This function creates a bipartite graph in which every possible edge is present.

Usage
```r
graph.full.bipartite(n1, n2, directed = FALSE, mode = c("all", "out", "in"))
```
Arguments

- **n1**: The number of vertices of the first kind.
- **n2**: The number of vertices of the second kind.
- **directed**: Logical scalar, whether the graphs is directed.
- **mode**: Scalar giving the kind of edges to create for directed graphs. If this is 'out' then all vertices of the first kind are connected to the others; 'in' specifies the opposite direction; 'all' creates mutual edges. This argument is ignored for undirected graphs.

Details

Bipartite graphs have a 'type' vertex attribute in igraph, this is boolean and FALSE for the vertices of the first kind and TRUE for vertices of the second kind.

Value

An igraph graph, with the 'type' vertex attribute set.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

See Also

- `graph.full` for creating one-mode full graphs

Examples

```r
g <- graph.full.bipartite(2, 3)
g2 <- graph.full.bipartite(2, 3, dir=TRUE)
g3 <- graph.full.bipartite(2, 3, dir=TRUE, mode="in")
g4 <- graph.full.bipartite(2, 3, dir=TRUE, mode="all")
```

Description

This function downloads a graph from a database created for the evaluation of graph isomorphism testing algorithms.

Usage

```r
graph.graphdb (url = NULL, prefix = "iso", type = "r001", nodes = NULL, pair = "A", which = 0, base = "http://cneurocvs.rmki.kfki.hu/graphdb/gzip", compressed = TRUE, directed = TRUE)
```
Arguments

- **url**: If not NULL it is a complete URL with the file to import.
- **prefix**: Gives the prefix. See details below. Possible values: `iso, i2, si4, si6, mcs10, mcs30, mcs50, mcs70, mcs90`
- **type**: Gives the graph type identifier. See details below. Possible values: `r001, r005, r01, r02, m2D, m2Dr2, m2Dr4, m2Dr6 m3D, m3Dr2, m3Dr4, m3Dr6, m4D, m4Dr2, m4Dr4, m4Dr6, b03, b06, b06m, b09, b09m`
- **nodes**: The number of vertices in the graph.
- **pair**: Specifies which graph of the pair to read. Possible values: A and B.
- **which**: Gives the number of the graph to read. For every graph type there are a number of actual graphs in the database. This argument specifies which one to read.
- **base**: The base address of the database. See details below.
- **compressed**: Logical constant, if TRUE then the file is expected to be compressed by gzip. If `url` is NULL then a `.gz` suffix is added to the filename.
- **directed**: Logical constant, whether to create a directed graph.

Details

graph.graphdb reads a graph from the graph database from an FTP or HTTP server or from a local copy. It has two modes of operation:

If the `url` argument is specified then it should the complete path to a local or remote graph database file. In this case we simply call `read.graph` with the proper arguments to read the file.

If `url` is NULL, and this is the default, then the filename is assembled from the base, prefix, type, nodes, pair and which arguments.

Unfortunately the original graph database homepage is now defunct, but see its old version at [http://web.archive.org/web/20090215182331/http://amalfi.dis.unina.it/graph/db/doc/graphdbat.html](http://web.archive.org/web/20090215182331/http://amalfi.dis.unina.it/graph/db/doc/graphdbat.html) for the actual format of a graph database file and other information.

Value

A new graph object.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

Examples

```r
## Not run:
g <- graph.graphdb(prefix="iso", type="r001", nodes=20, pair="A", which=10, compressed=TRUE)
g2 <- graph.graphdb(prefix="iso", type="r001", nodes=20, pair="B", which=10, compressed=TRUE)
graph.isomorphic.vf2(g, g2)
g3 <- graph.graphdb(url=paste(sep="/",
                      "http://cneurocvs.rmki.kfki.hu",
                      "graphdb/gzip/iso/bvg/b06m",
                      "iso_b06m_m200.a09.gz"))
## End(Not run)
```

description

`graph.incidence` creates a bipartite igraph graph from an incidence matrix.

Usage

```r
graph.incidence(incidence, directed = FALSE, mode = c("all", "out", "in", "total"), multiple = FALSE, weighted = NULL, add.names = NULL)
```

Arguments

- `incidence`: The input incidence matrix. It can also be a sparse matrix from the `Matrix` package.
- `directed`: Logical scalar, whether to create a directed graph.
- `mode`: A character scalar, defines the direction of the edges in directed graphs, ignored for undirected graphs. If ‘out’, then edges go from vertices of the first kind (corresponding to rows in the incidence matrix) to vertices of the second kind (columns in the incidence matrix). If ‘in’, then the opposite direction is used. If ‘all’ or ‘total’, then mutual edges are created.
- `multiple`: Logical scalar, specifies how to interpret the matrix elements. See details below.
- `weighted`: This argument specifies whether to create a weighted graph from the incidence matrix. If it is `NULL` then an unweighted graph is created and the multiple argument is used to determine the edges of the graph. If it is a character constant then for every non-zero matrix entry an edge is created and the value of the entry is added as an edge attribute named by the `weighted` argument. If it is `TRUE` then a weighted graph is created and the name of the edge attribute will be ‘weight’.
A character constant, NA or NULL. `graph.incidence` can add the row and column names of the incidence matrix as vertex attributes. If this argument is NULL (the default) and the incidence matrix has both row and column names, then these are added as the ‘name’ vertex attribute. If you want a different vertex attribute for this, then give the name of the attributes as a character string. If this argument is NA, then no vertex attributes (other than type) will be added.

Details
Bipartite graphs have a ‘type’ vertex attribute in igraph, this is boolean and FALSE for the vertices of the first kind and TRUE for vertices of the second kind.
`graph.incidence` can operate in two modes, depending on the `multiple` argument. If it is FALSE then a single edge is created for every non-zero element in the incidence matrix. If `multiple` is TRUE, then the matrix elements are rounded up to the closest non-negative integer to get the number of edges to create between a pair of vertices.

Value
A bipartite igraph graph. In other words, an igraph graph that has a vertex attribute type.

Author(s)
Gabor Csardi <csardi.gabor@gmail.com>

See Also
`graph.bipartite` for another way to create bipartite graphs

Examples
```r
inc <- matrix(sample(0:1, 15, repl=TRUE), 3, 5)
colnames(inc) <- letters[1:5]
rownames(inc) <- LETTERS[1:3]
graph.incidence(inc)
```

Description
The intersection of two or more graphs are created. The graphs may have identical or overlapping vertex sets.

Usage
`graph.intersection(..., byname = "auto", keep.all.vertices = TRUE)`
graph.intersection

Arguments

... 

byname 

A logical scalar, or the character scalar auto. Whether to perform the operation based on symbolic vertex names. If it is auto, that means TRUE if all graphs are named and FALSE otherwise. A warning is generated if auto and some (but not all) graphs are named.

keep.all.vertices 

Logical scalar, whether to keep vertices that only appear in a subset of the input graphs.

Details

graph.intersection creates the intersection of two or more graphs: only edges present in all graphs will be included. The corresponding operator is %s%.

If the byname argument is TRUE (or auto and all graphs are named), then the operation is performed on symbolic vertex names instead of the internal numeric vertex ids.

graph.intersection keeps the attributes of all graphs. All graph, vertex and edge attributes are copied to the result. If an attribute is present in multiple graphs and would result a name clash, then this attribute is renamed by adding suffixes: _1, _2, etc.

The name vertex attribute is treated specially if the operation is performed based on symbolic vertex names. In this case name must be present in all graphs, and it is not renamed in the result graph.

An error is generated if some input graphs are directed and others are undirected.

Value

A new graph object.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

Examples

```r
## Common part of two social networks
str(net1 %s% net2)
```
Description

Kautz graphs are labeled graphs representing the overlap of strings.

Usage

graph.kautz(m, n)

Arguments

m  Integer scalar, the size of the alphabet. See details below.
n  Integer scalar, the length of the labels. See details below.

Details

A Kautz graph is a labeled graph, vertices are labeled by strings of length \( n+1 \) above an alphabet with \( m+1 \) letters, with the restriction that every two consecutive letters in the string must be different. There is a directed edge from a vertex \( v \) to another vertex \( w \) if it is possible to transform the string of \( v \) into the string of \( w \) by removing the first letter and appending a letter to it.

Kautz graphs have some interesting properties, see e.g. Wikipedia for details.

Value

A graph object.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>, the first version in R was written by Vincent Matossian.

See Also

graph.de.bruijn, line.graph

Examples

line.graph(graph.kautz(2,1))
graph.kautz(2,2)
**graph.knn**

*Average nearest neighbor degree*

**Description**

Calculate the average nearest neighbor degree of the given vertices and the same quantity in the function of vertex degree.

**Usage**

`graph.knn(graph, vids=V(graph), weights=NULL)`

**Arguments**

- **graph**: The input graph. It can be directed, but it will be treated as undirected, i.e. the direction of the edges is ignored.
- **vids**: The vertices for which the calculation is performed. Normally it includes all vertices. Note, that if not all vertices are given here, then both `knn` and `knnk` will be calculated based on the given vertices only.
- **weights**: Weight vector. If the graph has a weight edge attribute, then this is used by default. If this argument is given, then vertex strength (see `graph.strength`) is used instead of vertex degree. But note that `knnk` is still given in the function of the normal vertex degree.

**Details**

Note that for zero degree vertices the answer in `knn` is `NaN` (zero divided by zero), the same is true for `knnk` if a given degree never appears in the network.

**Value**

A list with two members:

- **knn**: A numeric vector giving the average nearest neighbor degree for all vertices in `vids`.
- **knnk**: A numeric vector, its length is the maximum (total) vertex degree in the graph. The first element is the average nearest neighbor degree of vertices with degree one, etc.

**Author(s)**

Gabor Csardi `<csardi.gabor@gmail.com>`

**References**

Examples

# Some trivial ones
g <- graph.ring(10)
graph.knn(g)
g2 <- graph.star(10)
graph.knn(g2)

# A scale-free one, try to plot 'knnk'
g3 <- ba.game(1000, m=5)
graph.knn(g3)

# A random graph
g4 <- random.graph.game(1000, p=5/1000)
graph.knn(g4)

# A weighted graph
g5 <- graph.star(10)
E(g5)$weight <- seq(ecount(g5))
graph.knn(g5)

Description

The Laplacian of a graph.

Usage

graph.laplacian(graph, normalized=FALSE, weights=NULL,
sparse=getigraphOpt("sparsematrices"))

Arguments

graph The input graph.
normalized Whether to calculate the normalized Laplacian. See definitions below.
weights An optional vector giving edge weights for weighted Laplacian matrix. If this is NULL and the graph has an edge attribute called weight, then it will be used automatically. Set this to NA if you want the unweighted Laplacian on a graph that has a weight edge attribute.
sparse Logical scalar, whether to return the result as a sparse matrix. The Matrix package is required for sparse matrices.
The Laplacian Matrix of a graph is a symmetric matrix having the same number of rows and columns as the number of vertices in the graph. The element (i,j) is d[i], the degree of vertex i if i==j, -1 if i!=j and there is an edge between vertices i and j, and 0 otherwise.

A normalized version of the Laplacian Matrix is similar: element (i,j) is 1 if i==j, -1/sqrt(d[i] d[j]) if i!=j and there is an edge between vertices i and j, and 0 otherwise.

The weighted version of the Laplacian simply works with the weighted degree instead of the plain degree. I.e. (i,j) is d[i], the weighted degree of vertex i if i==j, -w if i!=j and there is an edge between vertices i and j with weight w, and 0 otherwise. The weighted degree of a vertex is the sum of the weights of its adjacent edges.

Value

A numeric matrix.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

Examples

```r
g <- graph.ring(10)
graph.laplacian(g)
graph.laplacian(g, norm=TRUE)
graph.laplacian(g, norm=TRUE, sparse=FALSE)
```

Description

LCF is short for Lederberg-Coxeter-Frucht, it is a concise notation for 3-regular Hamiltonian graphs. It consists of three parameters, the number of vertices in the graph, a list of shifts giving additional edges to a cycle backbone and another integer giving how many times the shifts should be performed. See [http://mathworld.wolfram.com/LCFNotation.html](http://mathworld.wolfram.com/LCFNotation.html) for details.

Usage

```r
graph.lcf(n, shifts, repeats)
```

Arguments

- `n` : Integer, the number of vertices in the graph.
- `shifts` : Integer vector, the shifts.
- `repeats` : Integer constant, how many times to repeat the shifts.
**graph.matching**

**Value**

A graph object.

**Author(s)**

Gabor Csardi <csardi.gabor@gmail.com>

**See Also**

graph can create arbitrary graphs, see also the other functions on the its manual page for creating special graphs.

**Examples**

```r
# This is the Franklin graph:
g1 <- graph.lcf(12, c(5,-5), 6)
g2 <- graph.famous("Franklin")
graph.isomorphic.vf2(g1, g2)
```

---

**Description**

A matching in a graph means the selection of a set of edges that are pairwise non-adjacent, i.e. they have no common incident vertices. A matching is maximal if it is not a proper subset of any other matching.

**Usage**

```r
is.matching(graph, matching, types = NULL)
is.maximal.matching(graph, matching, types = NULL)
maximum.bipartite.matching(graph, types = NULL, weights = NULL,
                          eps = .Machine$double.eps)
```

**Arguments**

- `graph`: The input graph. It might be directed, but edge directions will be ignored.
- `types`: Vertex types, if the graph is bipartite. By default they are taken from the ‘type’ vertex attribute, if present.
- `matching`: A potential matching. An integer vector that gives the pair in the matching for each vertex. For vertices without a pair, supply NA here.
- `weights`: Potential edge weights. If the graph has an edge attribute called ‘weight’, and this argument is NULL, then the edge attribute is used automatically.
eps  A small real number used in equality tests in the weighted bipartite matching algorithm. Two real numbers are considered equal in the algorithm if their difference is smaller than eps. This is required to avoid the accumulation of numerical errors. By default it is set to the smallest $x$, such that $1 + x \neq 1$ holds. If you are running the algorithm with no weights, this argument is ignored.

Details

is.matching checks a matching vector and verifies whether its length matches the number of vertices in the given graph, its values are between zero (inclusive) and the number of vertices (inclusive), and whether there exists a corresponding edge in the graph for every matched vertex pair. For bipartite graphs, it also verifies whether the matched vertices are in different parts of the graph.

is.maximal.matching checks whether a matching is maximal. A matching is maximal if and only if there exists no unmatched vertex in a graph such that one of its neighbors is also unmatched.

maximum.bipartite.matching calculates a maximum matching in a bipartite graph. A matching in a bipartite graph is a partial assignment of vertices of the first kind to vertices of the second kind such that each vertex of the first kind is matched to at most one vertex of the second kind and vice versa, and matched vertices must be connected by an edge in the graph. The size (or cardinality) of a matching is the number of edges. A matching is a maximum matching if there exists no other matching with larger cardinality. For weighted graphs, a maximum matching is a matching whose edges have the largest possible total weight among all possible matchings.

Maximum matchings in bipartite graphs are found by the push-relabel algorithm with greedy initialization and a global relabeling after every $n/2$ steps where $n$ is the number of vertices in the graph.

Value

is.matching and is.maximal.matching return a logical scalar.

maximum.bipartite.matching returns a list with components:

- matching.size  The size of the matching, i.e. the number of edges connecting the matched vertices.
- matching.weight  The weights of the matching, if the graph was weighted. For unweighted graphs this is the same as the size of the matching.
- matching  The matching itself. Numeric vertex id, or vertex names if the graph was named. Non-matched vertices are denoted by NA.

graph.maxflow

Maximum flow in a network

Description

In a graph where each edge has a given flow capacity the maximal flow between two vertices is calculated.

Usage

graph.maxflow(graph, source, target, capacity=NULL)
graph.mincut(graph, source=NULL, target=NULL, capacity=NULL,
value.only = TRUE)

Arguments

- **graph**: The input graph.
- **source**: The id of the source vertex.
- **target**: The id of the target vertex (sometimes also called sink).
- **capacity**: Vector giving the capacity of the edges. If this is NULL (the default) then the capacity edge attribute is used.
- **value.only**: Logical scalar, if TRUE only the minimum cut value is returned, if FALSE the edges in the cut and a the two (or more) partitions are also returned.

Details

graph.maxflow calculates the maximum flow between two vertices in a weighted (ie. valued) graph. A flow from source to target is an assignment of non-negative real numbers to the edges of the graph, satisfying two properties: (1) for each edge the flow (ie. the assigned number) is not more than the capacity of the edge (the capacity parameter or edge attribute), (2) for every vertex, except the source and the target the incoming flow is the same as the outgoing flow. The value of
the flow is the incoming flow of the target vertex. The maximum flow is the flow of maximum value.

graph.mincut calculates the minimum st-cut between two vertices in a graph (if the source and target arguments are given) or the minimum cut of the graph (if both source and target are NULL).

The minimum st-cut between source and target is the minimum total weight of edges needed to remove to eliminate all paths from source to target.

The minimum cut of a graph is the minimum total weight of the edges needed to remove to separate the graph into (at least) two components. (Which is to make the graph not strongly connected in the directed case.)

The maximum flow between two vertices in a graph is the same as the minimum st-cut, so graph.maxflow and graph.mincut essentially calculate the same quantity, the only difference is that graph.mincut can be invoked without giving the source and target arguments and then minimum of all possible minimum cuts is calculated.

For undirected graphs the Stoer-Wagner algorithm (see reference below) is used to calculate the minimum cut.

Value

For graph.maxflow a named list with components:

- **value**: A numeric scalar, the value of the maximum flow.
- **flow**: A numeric vector, the flow itself, one entry for each edge. For undirected graphs this entry is bit trickier, since for these the flow direction is not predetermined by the edge direction. For these graphs the elements of the this vector can be negative, this means that the flow goes from the bigger vertex id to the smaller one. Positive values mean that the flow goes from the smaller vertex id to the bigger one.
- **cut**: A numeric vector of edge ids, the minimum cut corresponding to the maximum flow.
- **partition1**: A numeric vector of vertex ids, the vertices in the first partition of the minimum cut corresponding to the maximum flow.
- **partition2**: A numeric vector of vertex ids, the vertices in the second partition of the minimum cut corresponding to the maximum flow.
- **stats**: A list with some statistics from the push-relabel algorithm. Five integer values currently: nopush is the number of push operations, norelabel the number of relabelings, nogap is the number of times the gap heuristics was used, nogapnodes is the total number of gap nodes omitted because of the gap heuristics and nobfs is the number of times a global breadth-first-search update was performed to assign better height (=distance) values to the vertices.

For graph.mincut a numeric constant, the value of the minimum cut, except if value.only=FALSE. In this case a named list with components:

- **value**: Numeric scalar, the cut value.
- **cut**: Numeric vector, the edges in the cut.
partition1  The vertices in the first partition after the cut edges are removed. Note that these vertices might be actually in different components (after the cut edges are removed), as the graph may fall apart into more than two components.

partition2  The vertices in the second partition after the cut edges are removed. Note that these vertices might be actually in different components (after the cut edges are removed), as the graph may fall apart into more than two components.

Examples

```r
E <- rbind( c(1,3,3), c(3,4,1), c(4,2,2), c(1,5,1), c(5,6,2), c(6,2,10))
colnames(E) <- c("from", "to", "capacity")
g1 <- graph.data.frame(as.data.frame(E))
graph.maxflow(g1, source=V(g1)["1"], target=V(g1)["2"])

g <- graph.ring(100)
graph.mincut(g, capacity=rep(1,vcount(g)))
graph.mincut(g, value.only=FALSE, capacity=rep(1,vcount(g)))

E2 <- graph( c(1,2,2,3,3,4, 1,6,6,5,5,4, 4,1) )
E2$capacity <- c(3,1,2, 10,1,3, 2)
g2 <- graph.mincut(g, value.only=FALSE)
```

<table>
<thead>
<tr>
<th>graph.strength</th>
<th>Strength or weighted vertex degree</th>
</tr>
</thead>
</table>

Description

Summing up the edge weights of the adjacent edges for each vertex.

Usage

```r
graph.strength (graph, vids = V(graph), mode = c("all", "out", "in", "total"), loops = TRUE, weights = NULL)```

graph.strength

Arguments

- **graph**: The input graph.
- **vids**: The vertices for which the strength will be calculated.
- **mode**: Character string, “out” for out-degree, “in” for in-degree or “all” for the sum of the two. For undirected graphs this argument is ignored.
- **loops**: Logical; whether the loop edges are also counted.
- **weights**: Weight vector. If the graph has a weight edge attribute, then this is used by default. If the graph does not have a weight edge attribute and this argument is NULL, then a warning is given and **degree** is called.

Value

A numeric vector giving the strength of the vertices.

**graph.structure**  
Method for structural manipulation of graphs

**Description**

These are the methods for simple manipulation of graphs: adding and deleting edges and vertices.

**Usage**

```r
## S3 method for class 'igraph'
x[i, j, ..., from, to,
sparse=getIgraphOpt("sparsematrices"),
edges=FALSE, drop=TRUE,
attr=if (is.weighted(x)) "weight" else NULL]
## S3 method for class 'igraph'
x[[i, j, ..., directed=TRUE, edges=FALSE, exact=TRUE]]
## S3 replacement method for class 'igraph'
x[i, j, ..., from, to,
attr=if (is.weighted(x)) "weight" else NULL] <- value

## S3 method for class 'igraph'
e1 + e2
## S3 method for class 'igraph'
e1 - e2
vertex(...)
vertices(...)
edge(...)
edges(...)
path(...)

add.edges(graph, edges, ..., attr=list())
add.vertices(graph, nv, ..., attr=list())
delete.edges(graph, edges)
delete.vertices(graph, v)
```

**Arguments**

- `x, graph, el`  
  The graph to work on.
- `i, j`  
  Vertex ids or names or logical vectors. See details below.
- `...`  
  These are currently ignored for the indexing operators. For `vertex`, `vertices`, `edge`, `edges` and `path` see details below. For `add.edges` and `add.vertices` these additional parameters will be added as edge/vertex attributes. Note that these arguments have to be named.
- `from`  
  A numeric or character vector giving vertex ids or names. Together with the `to` argument, it can be used to query/set a sequence of edges. See details below. This argument cannot be present together with any of the `i` and `j` arguments and if it is present, then the `to` argument must be present as well.
to A numeric or character vector giving vertex ids or names. Together with the from argument, it can be used to query/set a sequence of edges. See details below.

This argument cannot be present together with any of the i and j arguments and if it is present, then the from argument must be present as well.

sparse Logical scalar, whether to use sparse matrix.

directed Logical scalar, whether to consider edge directions in directed graphs. It is ignored for undirected graphs.

edges Logical scalar, whether to return edge ids.

drop_exact These arguments are ignored.

value A logical or numeric scalar or NULL. If FALSE, NULL or zero, then the specified edges will be deleted. If TRUE or a non-zero numeric value, then the specified edges will be added. (Only if they don’t yet exist.)

e2 See details below.

attr For the indexing operators: if not NULL, then it should be the name of an edge attribute. This attribute is queried, or updated to the given value. For add.edges and add.vertices: additional edge/vertex attributes to add. This will be concatenated to the other supplied attributes.

nv Numeric constant, the number of vertices to add.

v Vector sequence, the vertices to remove.

Details

There are, by and large, three ways to manipulate the structure of a graph in igraph. The first way is using the ‘[]’ and ‘[][]’ indexing operators on the graph object, very much like the graph was an adjacency matrix (‘[]’) or an adjacency list (‘[][]’). The single bracket indexes the (possibly weighted) adjacency matrix of the graph. The double bracket operator is similar, but queries the adjacency list of the graph. The details on how to use the indexing operators are discussed below.

The addition (‘+’) and division (‘-’) operators can also be used to add and remove vertices and edges. This form is sometimes more readable, and is usually the best if the user also wants to add attributes, together with the new vertices/edges. Please see the details below.

In addition, the four functions, add.vertices, add.edges, delete.vertices and delete.edges can also be used to manipulate the structure.

Value

For the indexing operators see the description above. The other functions return a new graph.

The indexing operators

The one-bracket (‘[]’) and two-brackets (‘[][]’) indexing operators allow relatively straightforward query and update operations on graphs. The one bracket operator works on the (imaginary) adjacency matrix of the graph. Here is what you can do with it:

1. Check whether there is an edge between two vertices (v and w) in the graph:
graph[v, w]
A numeric scalar is returned, one if the edge exists, zero otherwise.

2. Extract the (sparse) adjacency matrix of the graph, or part of it:

    graph[]
    graph[1:3,5:6]
    graph[c(1,3,5),]

The first variants returns the full adjacency matrix, the other two return part of it.

3. The from and to arguments can be used to check the existence of many edges. In this case, both from and to must be present and they must have the same length. They must contain vertex ids or names. A numeric vector is returned, of the same length as from and to, it contains ones for existing edges edges and zeros for non-existing ones. Example:

    graph[from=1:3, to=c(2,3,5)]

4. For weighted graphs, the [ operator returns the edge weights. For non-existent edges zero weights are returned. Other edge attributes can be queried as well, by giving the attr argument.

5. Querying edge ids instead of the existance of edges or edge attributes. E.g.

    graph[1, 2, edges=TRUE]

returns the id of the edge between vertices 1 and 2, or zero if there is no such edge.

6. Adding one or more edges to a graph. For this the element(s) of the imaginary adjacency matrix must be set to a non-zero numeric value (or TRUE):

    graph[1, 2] <- 1
    graph[1:3,1] <- 1
    graph[from=1:3, to=c(2,3,5)] <- TRUE

This does not affect edges that are already present in the graph, i.e. no multiple edges are created.

7. Adding weighted edges to a graph. The attr argument contains the name of the edge attribute to set, so it does not have to be 'weight':

    graph[1, 2, attr="weight"]<- 5
    graph[from=1:3, to=c(2,3,5)] <- c(1,-1,4)

If an edge is already present in the network, then only its weights or other attribute are updated. If the graph is already weighted, then the attr="weight" setting is implicit, and one does not need to give it explicitly.

8. Deleting edges. The replacement syntax allow the deletion of edges, by specifying FALSE or NULL as the replacement value:

    graph[v, w] <- FALSE

removes the edge from vertex v to vertex w. As this can be used to delete edges between two sets of vertices, either pairwise:

    graph[from=v, to=w] <- FALSE
or not:

\[
\text{graph}[v, w] \Leftarrow \text{FALSE}
\]

if \(v\) and \(w\) are vectors of edge ids or names.

The double bracket operator indexes the (imaginary) adjacency list of the graph. This can be used for the following operations:

1. Querying the adjacent vertices for one or more vertices:

\[
\text{graph}[1:3,]
\]

\[
\text{graph}[][1:3]
\]

The first form gives the successors, the second the predecessors or the 1:3 vertices. (For undirected graphs they are equivalent.)

2. Querying the incident edges for one or more vertices, if the \text{edges} argument is set to \text{TRUE}:

\[
\text{graph}[1:3, \text{edges=} \text{TRUE}]
\]

\[
\text{graph}[][1:3, \text{edges=} \text{TRUE}]
\]

3. Querying the edge ids between two sets or vertices, if both indices are used. E.g.

\[
\text{graph}[v, w, \text{edges=} \text{TRUE}]
\]

gives the edge ids of all the edges that exist from vertices \(v\) to vertices \(w\).

Both the '[' and '[['] operators allow logical indices and negative indices as well, with the usual R semantics. E.g.

\[
\text{graph[degree(graph) \text{==} 0, 1] \Leftarrow 1}
\]

adds an edge from every isolate vertex to vertex one, and

\[
G \Leftarrow \text{graph.empty(10)}
\]

\[
G[-1,1] \Leftarrow \text{TRUE}
\]

creates a star graph.

Of course, the indexing operators support vertex names, so instead of a numeric vertex id a vertex can also be given to '[' and '[['].

**The plus operator for adding vertices and edges**

The plus operator can be used to add vertices or edges to graph. The actual operation that is performed depends on the type of the right hand side argument.

- If is is another igraph graph object and they are both named graphs, then the union of the two graphs are calculated, see graph.union.
- If it is another igraph graph object, but either of the two are not named, then the disjoint union of the two graphs is calculated, see graph.disjoint.union.
- If it is a numeric scalar, then the specified number of vertices are added to the graph.
- If it is a character scalar or vector, then it is interpreted as the names of the vertices to add to the graph.
- If it is an object created with the vertex or vertices function, then new vertices are added to the graph. This form is appropriate when one wants to add some vertex attributes as well. The operands of the vertices function specifies the number of vertices to add and their attributes as well.

The unnamed arguments of vertices are concatenated and used as the 'name' vertex attribute (i.e. vertex names), the named arguments will be added as additional vertex attributes. Examples:

```r
g <- g + vertex(shape="circle", color="red")
g <- g + vertex("foo", color="blue")
g <- g + vertex("bar", "foobar")
g <- g + vertices("bar2", "foobar2", color=1:2, shape="rectangle")
```

See more examples below.

vertex is just an alias to vertices, and it is provided for readability. The user should use it if a single vertex is added to the graph.

- If it is an object created with the edge or edges function, then new edges will be added to the graph. The new edges and possibly their attributes can be specified as the arguments of the edges function.

The unnamed arguments of edges are concatenated and used as vertex ids of the end points of the new edges. The named arguments will be added as edge attributes. Examples:

```r
g <- graph.empty() + vertices(letters[1:10]) +
vertices("foo", "bar", "bar2", "foobar2")
g <- g + edge("a", "b")
g <- g + edges("foo", "bar", "bar2", "foobar2")
g <- g + edges(c("bar", "foo", "foobar2", "bar2"), color="red", weight=1:2)
```

See more examples below.

edge is just an alias to edges and it is provided for readability. The user should use it if a single edge is added to the graph.

- If it is an object created with the path function, then new edges that form a path are added. The edges and possibly their attributes are specified as the arguments to the path function. The non-named arguments are concatenated and interpreted as the vertex ids along the path. The remaining arguments are added as edge attributes. Examples:

```r
g <- graph.empty() + vertices(letters[1:10])
g <- g + path("a", "b", "c", "d")
g <- g + path("e", "f", "g", weight=1:2, color="red")
g <- g + path(c("f", "c", "j", "d"), width=1:3, color="green")
```

It is important to note that, although the plus operator is commutative, i.e. is possible to write

```r
graph <- "foo" + graph.empty()
```

it is not associative, e.g.

```r
graph <- "foo" + "bar" + graph.empty()
```
results a syntax error, unless parentheses are used:

```r
graph <- "foo" + ( "bar" + graph.empty() )
```

For clarity, we suggest to always put the graph object on the left hand side of the operator:

```r
graph <- graph.empty() + "foo" + "bar"
```

### The minus operator for deleting vertices and edges

The minus operator (’-’) can be used to remove vertices or edges from the graph. The operation performed is selected based on the type of the right hand side argument:

- If it is an igraph graph object, then the difference of the two graphs is calculated, see `graph.difference`.
- If it is a numeric or character vector, then it is interpreted as a vector of vertex ids and the specified vertices will be deleted from the graph. Example:
  ```r
g <- graph.ring(10)
V(g)$name <- letters[1:10]
g <- g - c("a", "b")
```
- If `e2` is a vertex sequence (e.g. created by the `V` function), then these vertices will be deleted from the graph.
- If it is an edge sequence (e.g. created by the `E` function), then these edges will be deleted from the graph.
- If it is an object created with the `vertex` (or the `vertices`) function, then all arguments of vertices are concatenated and the result is interpreted as a vector of vertex ids. These vertices will be removed from the graph.
- If it is an object created with the `edge` (or the `edges`) function, then all arguments of edges are concatenated and then interpreted as edges to be removed from the graph. Example:
  ```r
g <- graph.ring(10)
V(g)$name <- letters[1:10]
E(g)$name <- LETTERS[1:10]
g <- g - edge("e"|f")
g <- g - edge("H")
```
- If it is an object created with the `path` function, then all path arguments are concatenated and then interpreted as a path along which edges will be removed from the graph. Example:
  ```r
g <- graph.ring(10)
V(g)$name <- letters[1:10]
g <- g - path("a", "b", "c", "d")
```

### More functions to manipulate graph structure

`add.edges` adds the specified edges to the graph. The ids of the vertices are preserved. The additionally supplied named arguments will be added as edge attributes for the new edges. If an attribute was not present in the original graph, its value for the original edges will be `NA`.

`add.vertices` adds the specified number of isolate vertices to the graph. The ids of the old vertices are preserved. The additionally supplied named arguments will be added as vertex attributes for
the new vertices. If an attribute was not present in the original graph, its value is set to NA for the original vertices.
dele.edges removes the specified edges from the graph. If a specified edge is not present, the function gives an error message, and the original graph remains unchanged. The ids of the vertices are preserved.
dele.vertices removes the specified vertices from the graph together with their adjacent edges. The ids of the vertices are not preserved.

Gabor Csardi <csardi.gabor@gmail.com>

Examples

# 10 vertices named a,b,c,... and no edges
g <- graph.empty() + vertices(letters[1:10])

# Add edges to make it a ring
g <- g + path(letters[1:10], letters[1], color="grey")

# Add some extra random edges
g <- g + edges(sample(V(g), 10, replace=TRUE), color="red")
g$layout <- layout.circle
if (interactive()) {
  plot(g)
}

# The old-style operations
g <- graph.ring(10)
add.edges(g, c(2,6,3,7))
delete.edges(g, E(g, P=c(1,10, 2,3)))
delete.vertices(g, c(2,7,8))

---

**graph.union**  
*Union of graphs*

**Description**

The union of two or more graphs are created. The graphs may have identical or overlapping vertex sets.

**Usage**

```r
graph.union(..., byname = "auto")
```
Graphlets

Arguments

... Graph objects or lists of graph objects.

bname A logical scalar, or the character scalar auto. Whether to perform the operation based on symbolic vertex names. If it is auto, that means TRUE if all graphs are named and FALSE otherwise. A warning is generated if auto and some (but not all) graphs are named.

Details

graph.union creates the union of two or more graphs. Edges which are included in at least one graph will be part of the new graph. This function can be also used via the %u% operator.

If the bname argument is TRUE (or auto and all graphs are named), then the operation is performed on symbolic vertex names instead of the internal numeric vertex ids.

graph.union keeps the attributes of all graphs. All graph, vertex and edge attributes are copied to the result. If an attribute is present in multiple graphs and would result a name clash, then this attribute is renamed by adding suffixes: _1, _2, etc.

The name vertex attribute is treated specially if the operation is performed based on symbolic vertex names. In this case name must be present in all graphs, and it is not renamed in the result graph.

An error is generated if some input graphs are directed and others are undirected.

Value

A new graph object.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

Examples

## Union of two social networks with overlapping sets of actors
str(net1 %u% net2)

<table>
<thead>
<tr>
<th>Graphlets</th>
<th>Graphlet decomposition of a graph</th>
</tr>
</thead>
</table>

Description

Graphlet decomposition models a weighted undirected graph via the union of potentially overlapping dense social groups. This is done by a two-step algorithm. In the first step a candidate set of groups (a candidate basis) is created by finding cliques if the thresholded input graph. In the second step these the graph is projected on the candidate basis, resulting a weight coefficient for each clique in the candidate basis.
Usage

```r
graphlets (graph, weights = NULL, niter = 1000)
graphlets.candidate.basis (graph, weights = NULL)
graphlets.project (graph, weights = NULL, cliques, niter = 1000,
               Mu = rep(1, length(cliques)))
```

Arguments

- **graph**: The input graph, edge directions are ignored. Only simple graph (i.e. graphs without self-loops and multiple edges) are supported.
- **weights**: Edge weights. If the graph has a weight edge attribute and this argument is NULL (the default), then the weight edge attribute is used.
- **niter**: Integer scalar, the number of iterations to perform.
- **cliques**: A list of vertex ids, the graphlet basis to use for the projection.
- **Mu**: Starting weights for the projection.

Details

igraph contains three functions for performing the graph decomposition of a graph. The first is graphlets, which performed both steps on the method and returns a list of subgraphs, with their corresponding weights. The second and third functions correspond to the first and second steps of the algorithm, and they are useful if the user wishes to perform them individually: `graphlets.candidate.basis` and `graphlets.project`.

Value

- **graphlets**: returns a list with two members:
  - **cliques**: A list of subgraphs, the candidate graphlet basis. Each subgraph is give by a vector of vertex ids.
  - **Mu**: The weights of the subgraphs in graphlet basis.

- **graphlets.candidate.basis**: returns a list of two elements:
  - **cliques**: A list of subgraphs, the candidate graphlet basis. Each subgraph is give by a vector of vertex ids.
  - **thresholds**: The weight thresholds used for finding the subgraphs.

- **graphlets.project**: return a numeric vector, the weights of the graphlet basis subgraphs.

  sel <- gl$cliques[[i]]
  V(g)$color <- "white"
  V(g)[sel]$color <- "#E495A5"
  E(g)$width <- 1
  E(g)[ V(g)[sel] %--% V(g)[sel] ]$width <- 2
  E(g)$label <- ""
  E(g)[ width == 2 ]$label <- round(gl$mu[i], 2)
  E(g)$color <- "black"
  E(g)[ width == 2 ]$color <- "#E495A5"
  plot(g, layout=co)
}
```

Graphs from adjacency lists

Create graphs from adjacency lists

Description

An adjacency list is a list of numeric vectors, containing the neighbor vertices for each vertex. This function creates an igraph graph object from such a list.

Usage

```r
graph.adjlist(adjlist, mode = c("out", "in", "all", "total"),
              duplicate = TRUE)
```
Graphs from adjacency lists

Arguments

adjlist  The adjacency list. It should be consistent, i.e. the maximum throughout all vectors in the list must be less than the number of vectors (=the number of vertices in the graph). Note that the list is expected to be 0-indexed.

mode  Character scalar, it specifies whether the graph to create is undirected (‘all’ or ‘total’) or directed; and in the latter case, whether it contains the outgoing (‘out’) or the incoming (‘in’) neighbors of the vertices.

duplicate  Logical scalar. For undirected graphs it gives whether edges are included in the list twice. E.g. if it is TRUE then for an undirected \{A,B\} edge `graphNadjlist` expects A included in the neighbors of B and B to be included in the neighbors of A.

This argument is ignored if `mode` is out or in.

Details

Adjacency lists are handy if you intend to do many (small) modifications to a graph. In this case adjacency lists are more efficient than igraph graphs.

The idea is that you convert your graph to an adjacency list by `getNadjlist`, do your modifications to the graphs and finally create again an igraph graph by calling `graphNadjlist`.

Value

An igraph graph object.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

```
grg.game

Geometric random graphs

Description

Generate a random graph based on the distance of random point on a unit square.

Usage

grg.game(nodes, radius, torus = FALSE, coords = FALSE)

Arguments

- nodes: The number of vertices in the graph.
- radius: The radius within which the vertices will be connected by an edge.
- torus: Logical constant, whether to use a torus instead of a square.
- coords: Logical scalar, whether to add the positions of the vertices as vertex attributes called 'x' and 'y'.

Details

First a number of points are dropped on a unit square, these points correspond to the vertices of the graph to create. Two points will be connected with an undirected edge if they are closer to each other in Euclidean norm than a given radius. If the torus argument is TRUE then a unit area torus is used instead of a square.

Value

A graph object. If coords is TRUE then with vertex attributes 'x' and 'y'.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>, first version was written by Keith Briggs (http://keithbriggs.info/).

See Also

random.graph.game

Examples

g <- grg.game(1000, 0.05, torus=FALSE)
g2 <- grg.game(1000, 0.05, torus=TRUE)
Description
This function creates a random graph by simulating its stochastic evolution.

Usage
```r
growing.random.game(n, m = 1, directed = TRUE, citation = FALSE)
```

Arguments
- `n`: Numeric constant, number of vertices in the graph.
- `m`: Numeric constant, number of edges added in each time step.
- `directed`: Logical, whether to create a directed graph.
- `citation`: Logical. If TRUE a citation graph is created, i.e. in each time step the added edges are originating from the new vertex.

Details
This is discrete time step model, in each time step a new vertex is added to the graph and \( m \) new edges are created. If `citation` is FALSE these edges are connecting two uniformly randomly chosen vertices, otherwise the edges are connecting new vertex to uniformly randomly chosen old vertices.

Value
A new graph object.

Author(s)
Gabor Csardi `<csardi.gabor@gmail.com>`

See Also
- `barabasi.game`

Examples
```r
g <- growing.random.game(500, citation=FALSE)
g2 <- growing.random.game(500, citation=TRUE)
```
Hierarchical random graphs

Description

Fitting and sampling hierarchical random graph models.

Usage

```r
hrg.fit (graph, hrg = NULL, start = FALSE, steps = 0)
hrg.consensus (graph, hrg = NULL, start = FALSE, num.samples = 10000)

hrg.create (graph, prob)
hrg.dendrogram (hrg)

hrg.game (hrg)

hrg.predict (graph, hrg = NULL, start = FALSE, num.samples = 10000,
num.bins = 25)
```

## S3 method for class 'igraphHRG'

```r
print(x, type=c("auto", "tree", "plain"),
level = 3, ...)
```

## S3 method for class 'igraphHRGConsensus'

```r
print(x, ...)
```

Arguments

- **graph**
  The graph to fit the model to. Edge directions are ignored in directed graphs.

- **hrg**
  A hierarchical random graph model, in the form of an `igraphHRG` object. `hrg.fit` allows this to be `NULL`, in which case a random starting point is used for the fitting. `hrg.consensus` and `hrg.predict` allow this to be `NULL` as well, then a HRG is fitted to the graph first, from a random starting point.

- **start**
  Logical, whether to start the fitting/sampling from the supplied `igraphHRG` object, or from a random starting point.

- **steps**
  The number of MCMC steps to make. If this is zero, then the MCMC procedure is performed until convergence.

- **num.samples**
  Number of samples to use for consensus generation or missing edge prediction.

- **prob**
  A vector of probabilities, one for each vertex, in the order of vertex ids.

- **num.bins**
  Number of bins for the edge probabilities. Give a higher number for a more accurate prediction.

- **x**
  `igraphHRG` or `igraphHRGConsensus` object to print.

- **type**
  How to print the dendrogram, see details below.

- **level**
  The number of top levels to print from the dendrogram.

- **...**
  Additional arguments, not used currently.
Details

A hierarchical random graph is an ensemble of undirected graphs with \( n \) vertices. It is defined via a binary tree with \( n \) leaf and \( n - 1 \) internal vertices, where the internal vertices are labeled with probabilities. The probability that two vertices are connected in the random graph is given by the probability label at their closest common ancestor.

Please see references below for more about hierarchical random graphs.

igraph contains functions for fitting HRG models to a given network (`hrg.fit`), for generating networks from a given HRG ensemble (`hrg.game`), converting an igraph graph to a HRG and back (`hrg.create`, `hrg.dendrogram`), for calculating a consensus tree from a set of sampled HRGs (`hrg.consensus`) and for predicting missing edges in a network based on its HRG models (`hrg.predict`).

The igraph HRG implementation is heavily based on the code published by Aaron Clauset, at his website, [http://tuvalu.santafe.edu/~aaronc/hierarchy/](http://tuvalu.santafe.edu/~aaronc/hierarchy/).

`hrg.fit` fits a HRG to a given graph. It takes the specified steps number of MCMC steps to perform the fitting, or a convergence criteria if the specified number of steps is zero. `hrg.fit` can start from a given HRG, if this is given in the `hrg` argument and the `start` argument is `TRUE`.

`hrg.consensus` creates a consensus tree from several fitted hierarchical random graph models, using phylogeny methods. If the `hrg` argument is given and `start` is set to `TRUE`, then it starts sampling from the given HRG. Otherwise it optimizes the HRG log-likelihood first, and then samples starting from the optimum.

`hrg.create` creates a HRG from an igraph graph. The igraph graph must be a directed binary tree, with \( n - 1 \) internal and \( n \) leaf vertices. The `prob` argument contains the HRG probability labels for each vertex; these are ignored for leaf vertices.

`hrg.dendrogram` creates the corresponding igraph tree of a hierarchical random graph model.

`hrg.game` samples a graph from a given hierarchical random graph model.

`hrg.predict` uses a hierarchical random graph model to predict missing edges from a network. This is done by sampling hierarchical models around the optimum model, proportionally to their likelihood. The MCMC sampling is stated from `hrg`, if it is given and the `start` argument is set to `TRUE`. Otherwise a HRG is fitted to the graph first.

Value

`hrg.fit` returns an `igraphHRG` object. This is a list with the following members:

- `left` Vector that contains the left children of the internal tree vertices. The first vertex is always the root vertex, so the first element of the vector is the left child of the root vertex. Internal vertices are denoted with negative numbers, starting from -1 and going down, i.e. the root vertex is -1. Leaf vertices are denoted by non-negative number, starting from zero and up.

- `right` Vector that contains the right children of the vertices, with the same encoding as the `left` vector.

- `prob` The connection probabilities attached to the internal vertices, the first number belongs to the root vertex (i.e. internal vertex -1), the second to internal vertex -2, etc.

- `edges` The number of edges in the subtree below the given internal vertex.
Hierarchical random graphs

vertices

The number of vertices in the subtree below the given internal vertex, including itself.

hrg.conensus returns a list of two objects. The first is an igraphHRGConsensus object, the second is an igraphHRG object. The igraphHRGConsensus object has the following members:

parents

For each vertex, the id of its parent vertex is stored, or zero, if the vertex is the root vertex in the tree. The first n vertex ids (from 0) refer to the original vertices of the graph, the other ids refer to vertex groups.

weights

Numeric vector, counts the number of times a given tree split occured in the generated network samples, for each internal vertices. The order is the same as in the parents vector.

hrg.create returns an igraphHRG object.

hrg.dendrogram returns an igraph graph.

hrg.game returns an igraph graph.

Printing HRGs to the screen

igraphHRG objects can be printed to the screen in two forms: as a tree or as a list, depending on the type argument of the print function. By default the auto type is used, which selects tree for small graphs and simple (=list) for bigger ones. The tree format looks like this:

Hierarchical random graph, at level 3:

g1 p= 0
' - g15 p=0.33 1
' - g13 p=0.88 6 3 9 4 2 10 7 5 8
' - g8  p= 0.5
' - g16 p= 0.2 20 14 17 19 11 15 16 13
' - g5 p= 0 12 18

This is a graph with 20 vertices, and the top three levels of the fitted hierarchical random graph are printed. The root node of the HRG is always vertex group #1 ('g1' in the the printout). Vertex pairs in the left subtree of g1 connect to vertices in the right subtree with probability zero, according to the fitted model. g1 has two subgroups, g15 and g8. g15 has a subgroup of a single vertex (vertex 1), and another larger subgroup that contains vertices 6, 3, etc. on lower levels, etc.

The plain printing is simpler and faster to produce, but less visual:

Hierarchical random graph:

g1 p=0.0 -> g12 g10  g2 p=1.0 -> 7 10  g3 p=1.0 -> g18 14

It lists the two subgroups of each internal node, in as many columns as the screen width allows.

Consensus dendrograms (igraphHRGConsensus objects) are printed simply by listing the children of each internal node of the dendrogram:
igraph console

HHRG consensus tree:
g1 -> 11 12 13 14 15 16 17 18 19 20
g2 -> 1 2 3 4 5 6 7 8 9 10
g3 -> g1 g2

The root of the dendrogram is g3 (because it has no incoming edges), and it has two subgroups, g1 and g2.

hrg

## The consensus tree for it
hrg.consensus(g, hrg=hrg, start=TRUE)

## Prediction of missing edges
hrg.predict(g2)

## End(Not run)

igraph console
The igraph console

Description

The igraph console is a GUI windows that shows what the currently running igraph function is doing.
Usage

```r
igraph.console()
```

Details

The console can be started by calling the `igraph.console` function. Then it stays open, until the user closes it.

Another way to start it is to set the `verbose` igraph option to “tkconsole” via `igraph.options`. Then the console (re)opens each time an igraph function supporting it starts; to close it, set the `verbose` option to another value.

The console is written in Tcl/Tk and required the tcltk package.

Value

NULL, invisibly.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

See Also

`igraph.options` and the `verbose` option.

igraph options

Parameters for the igraph package

Description

igraph has some parameters which (usually) affect the behavior of many functions. These can be set for the whole session via `igraph.options`.

Usage

```r
igraph.options(...)  
getIgraphOpt(x, default = NULL)  
igraph.par(parid, parvalue = NULL)
```

Arguments

- `...` A list may be given as the only argument, or any number of arguments may be in the name=value form, or no argument at all may be given. See the Value and Details sections for explanation.
- `x` A character string holding an option name.
- `default` If the specified option is not set in the options list, this value is returned. This facilitates retrieving an option and checking whether it is set and setting it separately if not.
igraph options

parid            The name of the parameter. See the currently used parameters below.
parvalue         The new value of the parameter. If NULL then the current value of the parameter
                 is listed.

Details

From igraph version 0.6, igraph.par is deprecated. Please use the more flexible igraph.options
and getIgraphOpt functions instead.

The parameter values set via a call to the igraph.options function will remain in effect for the
rest of the session, affecting the subsequent behaviour of the other functions of the igraph package
for which the given parameters are relevant.

This offers the possibility of customizing the functioning of the igraph package, for instance by
insertions of appropriate calls to igraph.options in a load hook for package igraph.

The currently used parameters in alphabetical order:

add.params      Logical scalar, whether to add model parameter to the graphs that are created by the
                 various graph constructors. By default it is TRUE.
add.vertex.names Logical scalar, whether to add vertex names to node level indices, like degree,
                 betweenness scores, etc. By default it is TRUE.
annotate.plot    Logical scalar, whether to annotate igraph plots with the graph's name (name graph
                 attribute, if present) as main, and with the number of vertices and edges as xlab. Defaults to
                 FALSE.
dend.plot.type   The plotting function to use when plotting community structure dendrograms via
dendPlot. Possible values are 'auto' (the default), 'phylo', 'hclust' and 'dendrogram'. See
dendPlot for details.
edge.attr.comb   Specifies what to do with the edge attributes if the graph is modified. The default
                 value is list(weight="sum", name="concat", "ignore"). See attribute.combination
                 for details on this.
nexus.url        The base URL of the default Nexus server. See nexus for details.
print.edge.attributes Logical constant, whether to print edge attributes when printing graphs. De-
                         fault to FALSE.
print.full        Logical scalar, whether print.igraph should show the graph structure as well, or only
                 a summary of the graph.
print.graph.attributes Logical constant, whether to print graph attributes when printing graphs.
                        Defaults to FALSE.
print.vertex.attributes Logical constant, whether to print vertex attributes when printing graphs.
                         Defaults to FALSE.
sparsematrices   Whether to use the Matrix package for (sparse) matrices. It is recommended, if
                 the user works with larger graphs.
verbose          Logical constant, whether igraph functions should talk more than minimal. Eg. if TRUE
                 thne some functions will use progress bars while computing. Defaults to FALSE.
vertex.attr.comb Specifies what to do with the vertex attributes if the graph is modified. The
default value is list(name="concat", "ignore") See attribute.combination for details
                 on this.
igraph.sample

Value

igraph.options returns a list with the updated values of the parameters. If the argument list is not empty, the returned list is invisible.

For getIgraphOpt, the current value set for option x, or NULL if the option is unset.

If parvalue is NULL then igraph.par returns the current value of the parameter. Otherwise the new value of the parameter is returned invisibly.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

See Also

igraph.options is similar to options and getIgraphOpt is similar to getOption.

Examples

oldval <- getIgraphOpt("verbose")
igraph.options(verbosetrue)
layout.kamada.kawai(graph.ring(10))
igraph.options(verbosetoldval)

igraph.sample Sampling a random integer sequence

Description

This function provides a very efficient way to pull an integer random sample sequence from an integer interval.

Usage

igraph.sample(low, high, length)

Arguments

low The lower limit of the interval (inclusive).
high The higher limit of the interval (inclusive).
length The length of the sample.

Details

The algorithm runs in \(O(\text{length})\) expected time, even if high-low is big. It is much faster (but of course less general) than the builtin sample function of R.
Value

An increasing numeric vector containing integers, the sample.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

References

Examples

```r
rs <- igraph.sample(1, 100000000, 10)
rs
```

Description

These functions are still in the alpha stage or their arguments are expected to change, so they’re not documented yet. They are also not very useful for the general audience.

Usage

```r
lastcit.game(n, edges=1, agebins=n/7100, pref=(1:(agebins+1))^3, directed=TRUE)
cited.type.game(n, edges=1, types=rep(0, n),
  pref=rep(1, length(types)),
  directed=TRUE, attr=TRUE)
citing.cited.type.game(n, edges=1, types=rep(0, n),
  pref=matrix(1, nrow=length(types), ncol=length(types)),
  directed=TRUE, attr=TRUE)
```

Arguments

- `n` Number of vertices.
- `edges` Number of edges per step.
- `agebins` Number of aging bins.
- `pref` Vector (lastcit.game and cited.type.game or matrix(citing.cited.type.game) giving the (unnormalized) citation probabilities for the different vertex types.
- `directed` Logical scalar, whether to generate directed networks.
- `types` Vector of length ‘n’, the types of the vertices. Types are numbered from zero.
- `attr` Logical scalar, whether to add the vertex types to the generated graph as a vertex attribute called ‘type’.
igraph.version

Value
A new graph.

Author(s)
Gabor Csardi <csardi.gabor@gmail.com>

---

igraph.version | Query igraph's version string

Description
Queries igraph's original version string. See details below.

Usage
igraph.version()

Details
The igraph version string is the same as the version of the R package for all released igraph versions. For development versions and nightly builds, they might differ however.

The reason for this is, that R package version numbers are not flexible enough to cover in-between releases versions, e.g. alpha and beta versions, release candidates, etc.

Value
A character scalar, the igraph version string.

Author(s)
Gabor Csardi <csardi.gabor@gmail.com>

Examples
```r
## Compare to the package version
packageDescription("igraph")$Version
igraph.version()
```
igraphdemo

Run igraph demos, step by step

Description
Run one of the accompanying igraph demos, somewhat interactively, using a Tk window.

Usage
igraphdemo(which)

Arguments
which
If not given, then the names of the available demos are listed. Otherwise it should be either a filename or the name of an igraph demo.

Details
This function provides a somewhat nicer interface to igraph demos that come with the package, than the standard demo function. Igraph demos are divided into chunks and igraphdemo runs them chunk by chunk, with the possibility of inspecting the workspace between two chunks.
The tcltk package is needed for igraphdemo.

Value
Returns NULL, invisibly.

Author(s)
Gabor Csardi <csardi.gabor@gmail.com>

See Also
demo

Examples
igraphdemo()
if (interactive()) {
    igraphdemo("centrality")
}
igraph.test  

**Run package tests**

**Description**

Runs all package tests.

**Usage**

```r
igraph.test()
```

**Details**

The testthat package is needed to run all tests. The location tests themselves can be extracted from the package via `system.file("tests", package="igraph")`.

This function simply calls the `test_dir` function from the testthat package on the test directory.

**Value**

Whatever is returned by `test_dir` from the testthat package.

**Author(s)**

Gabor Csardi <csardi.gabor@gmail.com>

---

**independent.vertex.sets**

**Independent vertex sets**

**Description**

A vertex set is called independent if there no edges between any two vertices in it. These functions find independent vertex sets in undirected graphs.

**Usage**

```r
independent.vertex.sets(graph, min=NULL, max=NULL)
largest.independent.vertex.sets(graph)
maximal.independent.vertex.sets(graph)
independence.number(graph)
```
Arguments

graph  The input graph, directed graphs are considered as undirected, loop edges and multiple edges are ignored.

min  Numeric constant, limit for the minimum size of the independent vertex sets to find. NULL means no limit.

max  Numeric constant, limit for the maximum size of the independent vertex sets to find. NULL means no limit.

Details

independent.vertex.sets finds all independent vertex sets in the network, obeying the size limitations given in the min and max arguments.

largest.independent.vertex.sets finds the largest independent vertex sets in the graph. An independent vertex set is largest if there is no independent vertex set with more vertices.

maximal.independent.vertex.sets finds the maximal independent vertex sets in the graph. An independent vertex set is maximal if it cannot be extended to a larger independent vertex set. The largest independent vertex sets are maximal, but the opposite is not always true.

independence.number calculate the size of the largest independent vertex set(s).

These functions use the algorithm described by Tsukiyama et al., see reference below.

Value

independent.vertex.sets, largest.independent.vertex.sets and maximal.independent.vertex.sets return a list containing numeric vertex ids, each list element is an independent vertex set.

independence.number returns an integer constant.

Author(s)

Tamas Nepusz <ntamas@gmail.com> ported it from the Very Nauty Graph Library by Keith Briggs (http://keithbriggs.info/) and Gabor Csardi <csardi.gabor@gmail.com> wrote the R interface and this manual page.

cliques

Examples

# A quite dense graph
set.seed(42)
g <- erdos.renyi.game(100, 0.9)
independence.number(g)
Description

Find community structure that minimizes the expected description length of a random walker trajectory

Usage

infomap.community (graph, e.weights = NULL, v.weights = NULL, nb.trials = 10, modularity = TRUE)

Arguments

graph The input graph.
e.weights If not NULL, then a numeric vector of edge weights. The length must match the number of edges in the graph. By default the 'weight' edge attribute is used as weights. If it is not present, then all edges are considered to have the same weight.
v.weights If not NULL, then a numeric vector of vertex weights. The length must match the number of vertices in the graph. By default the 'weight' vertex attribute is used as weights. If it is not present, then all vertices are considered to have the same weight.
nb.trials The number of attempts to partition the network (can be any integer value equal or larger than 1).
modularity Logical scalar, whether to calculate the modularity score of the detected community structure.

Details

Please see the details of this method in the references given below.

Value

infomap.community returns a communities object, please see the communities manual page for details.
Author(s)

Martin Rosvall (http://www.tpu.umi.se/~rosvall/) wrote the original C++ code. This was ported to be more igraph-like by Emmanuel Navarro (http://www.irit.fr/~Emmanuel.Navarro/). The R interface and some cosmetics was done by Gabor Csardi <csardi.gabor@gmail.com>.

---

**interconnected.islands**

*A graph with subgraphs that are each a random graph.*

Description

Create a number of Erdos-Renyi random graphs with identical parameters, and connect them with the specified number of edges.

Usage

`interconnected.islands.game(islands.n, islands.size, islands.pin, n.inter)`

Arguments

- `islands.n`: The number of islands in the graph.
- `islands.size`: The size of islands in the graph.
- `islands.pin`: The probability to create each possible edge into each island.
- `n.inter`: The number of edges to create between two islands.
is.chordal

Value

An igraph graph.

Author(s)

Samuel Thiriot (http://samuelthiriot.res-ear.ch/)

See Also

erdos.renyi.game

Examples

```r
  g <- interconnected.islands.game(3, 10, 5/10, 1)
  oc <- optimal.community(g)
  oc
```

---

**is.chordal**  
*Chordality of a graph*

Description

A graph is chordal (or triangulated) if each of its cycles of four or more nodes has a chord, which is an edge joining two nodes that are not adjacent in the cycle. An equivalent definition is that any chordless cycles have at most three nodes.

Usage

```r
  is.chordal(graph, alpha = NULL, alpham1 = NULL, fillin = FALSE, newgraph = FALSE)
```

Arguments

- **graph**: The input graph. It may be directed, but edge directions are ignored, as the algorithm is defined for undirected graphs.
- **alpha**: Numeric vector, the maximal chardinality ordering of the vertices. If it is NULL, then it is automatically calculated by calling `maximum.cardinality.search`, or from `alpham1` if that is given.
- **alpham1**: Numeric vector, the inverse of `alpha`. If it is NULL, then it is automatically calculated by calling `maximum.cardinality.search`, or from `alpha`.
- **fillin**: Logical scalar, whether to calculate the fill-in edges.
- **newgraph**: Logical scalar, whether to calculate the triangulated graph.
Details

The chordality of the graph is decided by first performing maximum cardinality search on it (if the alpha andalpham1 arguments are NULL), and then calculating the set of fill-in edges.

The set of fill-in edges is empty if and only if the graph is chordal.

It is also true that adding the fill-in edges to the graph makes it chordal.

Value

A list with three members:

- **chordal** Logical scalar, it is TRUE iff the input graph is chordal.
- **fillin** If requested, then a numeric vector giving the fill-in edges. NULL otherwise.
- **newgraph** If requested, then the triangulated graph, an igraph object. NULL otherwise.

I-A:H)
m <- maximum.cardinality.search(g1)  
is.chordal(m, fillin=TRUE)

# Examples from tarjanMyannakakis paper

g2 <- graph.formula(A-B:E, B-A:E:F:D, C-E:D:G, D-B:F:E:C:G,  
m <- maximum.cardinality.search(g2)  
is.chordal(g2, fillin=TRUE)
```
is.dag

**Description**

This function tests whether the given graph is a DAG, a directed acyclic graph.

**Usage**

is.dag(graph)

**Arguments**

- **graph**
  
  The input graph. It may be undirected, in which case FALSE is reported.

**Details**

is.dag checks whether there is a directed cycle in the graph. If not, the graph is a DAG.

**Value**

A logical vector of length one.

**Author(s)**

Tamas Nepusz <ntamas@gmail.com> for the C code, Gabor Csardi <csardi.gabor@gmail.com> for the R interface.

**Examples**

```r
  g <- graph.tree(10)
  is.dag(g)
  g2 <- g + edge(5,1)
  is.dag(g2)
```

---

is.degree.sequence

**Description**

These functions decide whether a sequence (or two, if the graph is directed) of integers can be realized as vertex degrees by a graph or simple graph.

**Usage**

- is.degree.sequence (out.deg, in.deg = NULL)
- is.graphical.degree.sequence (out.deg, in.deg = NULL)
is.igraph

Arguments

out.degree Integer vector, the degree sequence for undirected graphs, or the out-degree sequence for directed graphs.

in.degree NULL or an integer vector. For undirected graphs, it should be NULL. For directed graphs it specifies the in-degrees.

Details

is.degree.sequence checks whether the given vertex degrees (in- and out-degrees for directed graphs) can be realized by a graph. Note that the graph does not have to be simple, it may contain loop and multiple edges. For undirected graphs, it also checks whether the sum of degrees is even. For directed graphs, the function checks whether the lengths of the two degree vectors are equal and whether their sums are also equal. These are known sufficient and necessary conditions for a degree sequence to be valid.

is.graphical.degree.sequence determines whether the given vertex degrees (in- and out-degrees for directed graphs) can be realized in a simple graph, i.e. a graph without multiple or loop edges.

Value

A logical scalar.

Author(s)

Tamas Nepusz <ntamas@gmail.com>

References

Examples

g <- erdos.renyi.game(100, 2/100)
is.degree.sequence(degree(g))
is.graphical.degree.sequence(degree(g))

---

is.igraph

Is this object a graph?

Description

is.graph makes its decision based on the class attribute of the object.
is.multiple

Usage

is.igraph(graph)

Arguments

graph An R object.

Value

A logical constant, TRUE if argument graph is a graph object.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

Examples

g <- graph.ring(10)
is.igraph(g)
is.igraph(numeric(10))

is.multiple Find the multiple or loop edges in a graph

Description

A loop edge is an edge from a vertex to itself. An edge is a multiple edge if it has exactly the same head and tail vertices as another edge. A graph without multiple and loop edges is called a simple graph.

Usage

is.loop(graph, eids=E(graph))
has.multiple(graph)
is.multiple(graph, eids=E(graph))
count.multiple(graph, eids=E(graph))

Arguments

graph The input graph.
eids The edges to which the query is restricted. By default this is all edges in the graph.
Details

`is.loop` decides whether the edges of the graph are loop edges.

`has.multiple` decides whether the graph has any multiple edges.

`is.multiple` decides whether the edges of the graph are multiple edges.

`count.multiple` counts the multiplicity of each edge of a graph.

Note that the semantics for `is.multiple` and `count.multiple` is different. `is.multiple` gives TRUE for all occurrences of a multiple edge except for one. I.e. if there are three i-j edges in the graph then `is.multiple` returns TRUE for only two of them while `count.multiple` returns ‘3’ for all three.

See the examples for getting rid of multiple edges while keeping their original multiplicity as an edge attribute.

Value

`has.multiple` returns a logical scalar. `is.loop` and `is.multiple` return a logical vector. `count.multiple` returns a numeric vector.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

See Also

`simplify` to eliminate loop and multiple edges.

Examples

```r
# Loops
g <- graph( c(1,1,2,2,3,3,4,5) )
is.loop(g)

# Multiple edges
g <- barabasi.game(10, m=3, algorithm="bag")
has.multiple(g)
is.multiple(g)
count.multiple(g)
is.multiple(simplify(g))
all(count.multiple(simplify(g)) == 1)

# Direction of the edge is important
is.multiple(graph( c(1,2, 2,1) ))
is.multiple(graph( c(1,2, 2,1), dir=FALSE ))

# Remove multiple edges but keep multiplicity
E(g)$weight <- count.multiple(g)
g <- simplify(g)
any(is.multiple(g))
E(g)$weight
```
is.mutual  

Find mutual edges in a directed graph

Description
This function checks the reciproc pair of the supplied edges.

Usage

is.mutual(graph, es = E(graph))

Arguments

graph The input graph.
es Edge sequence, the edges that will be probed. By default is includes all edges in
the order of their ids.

Details
In a directed graph an (A,B) edge is mutual if the graph also includes a (B,A) directed edge.
Note that multi-graphs are not handled properly, i.e. if the graph contains two copies of (A,B) and
one copy of (B,A), then these three edges are considered to be mutual.
Undirected graphs contain only mutual edges by definition.

Value
A logical vector of the same length as the number of edges supplied.

Author(s)
Gabor Csardi <csardi.gabor@gmail.com>

See Also
reciprocity, dyad.census if you just want some statistics about mutual edges.

Examples

g <- erdos.renyi.game(10,50,type="gnm",directed=TRUE)
reciprocity(g)
dyad.census(g)
is.mutual(g)
sum(is.mutual(g))/2 == dyad.census(g)$mut
Description

An igraph graph is named, if there is a symbolic name associated with its vertices.

Usage

is.named(graph)

Arguments

graph The input graph.

Details

In igraph vertices can always be identified and specified via their numeric vertex ids. This is, however, not always convenient, and in many cases there exist symbolic ids that correspond to the vertices. To allow this more flexible identification of vertices, one can assign a vertex attribute called ‘name’ to an igraph graph. After doing this, the symbolic vertex names can be used in all igraph functions, instead of the numeric ids.

Note that the uniqueness of vertex names are currently not enforced in igraph, you have to check that for yourself, when assigning the vertex names.

Value

A logical scalar.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

Examples

g <- graph.ring(10)
is.named(g)
V(g)$name <- letters[1:10]
is.named(g)
neighbors(g, "a")
is.separor

Vertex separators

Description

These functions check whether a given set of vertices is a vertex separator, or a minimal vertex.separator.

Usage

is.separator(graph, candidate)

is.minimal.separator(graph, candidate)

Arguments

graph The input graph. It may be directed, but edge directions are ignored.

candidate A numeric vector giving the vertex ids of the candidate separator.

Details

is.separator decides whether the supplied vertex set is a vertex separator. A vertex set is a vertex separator if its removal results a disconnected graph.

is.minimal.separator decides whether the supplied vertex set is a minimal vertex separator. A minimal vertex separator is a vertex separator, such that none of its subsets is a vertex separator.

In the special case of a fully connected graph with \( n \) vertices, each set of \( n - 1 \) vertices is considered to be a vertex separator.

Value

A logical scalar, whether the supplied vertex set is a (minimal) vertex separator or not.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

See Also

minimum.size.separators lists all vertex separator of minimum size.

Examples

# The graph from the Moody-White paper

is.weighted

Description

In weighted graphs, a real number is assigned to each (directed or undirected) edge.

Usage

is.weighted(graph)

Arguments

graph The input graph.

Details

In igraph edge weights are represented via an edge attribute, called ‘weight’. The is.weighted function only checks that such an attribute exists. (It does not even checks that it is a numeric edge attribute.)

Edge weights are used for different purposes by the different functions. E.g. shortest path functions use it as the cost of the path; community finding methods use it as the strength of the relationship between two vertices, etc. Check the manual pages of the functions working with weighted graphs for details.

Value

A logical scalar.
Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

Examples

```r
g <- graph.ring(10)
get.shortest.paths(g, 8, 2)
E(g)$weight <- seq_len(ecount(g))
get.shortest.paths(g, 8, 2)
```

Description

Vertex and edge sequences are central concepts of igraph.

Usage

```r
V(graph)
E(graph, P=NULL, path=NULL, directed=TRUE)
```

Arguments

- `graph` A graph object.
- `P` Numeric vector for selecting edges by giving their end points. See details below.
- `path` Numeric vector, this is for selecting all edges along a path. See also details below.
- `directed` Logical constant, can be supplied only if either `P` or `path` is also present and gives whether the pairs or the path are directed or not.

Details

One often needs to perform an operation on a subset of vertices of edges in a graph.

A vertex sequence is simply a vector containing vertex ids, but it has a special class attribute which makes it possible to perform graph specific operations on it, like selecting a subset of the vertices based on some vertex attributes.

A vertex sequence is created by `V(g)` this selects are vertices in increasing vertex id order. A vertex sequence can be indexed by a numeric vector, and a subset of all vertices can be selected.

Vertex sequences provide powerful operations for dealing with vertex attributes. A vertex sequence can be indexed with the `$` operator to select (or modify) the attributes of a subset of vertices. A vertex sequence can be indexed by a logical expression, and this expression may contain the names of the vertex attributes and ordinary variables as well. The return value of such a construct (ie. a vertex sequence indexed by a logical expression) is another vertex sequence containing only vertices from the original sequence for which the expression evaluates to TRUE.
Let us see an example to make everything clear. We assign random numbers between 1 and 100 to the vertices, and select those vertices for which the number is less than 50. We set the color of these vertices to red.

```r
g <- graph.ring(10)
V(g)$number <- sample(1:100, vcount(g), replace=TRUE)
V(g)$color <- "grey"
V(g)[ number < 50 ]$color <- "red"
plot(g, layout=layout.circle, vertex.color=V(g)$color,
     vertex.label=V(g)$number)
```

There is a similar notation for edges. E(g) selects all edges from the ‘g’ graph. Edge sequences can be also indexed with logical expressions containing edge attributes:

```r
g <- graph.ring(10)
E(g)$weight <- runif(ecount(g))
E(g)$width <- 1
E(g)[ weight >= 0.5 ]$width <- 3
plot(g, layout=layout.circle, edge.width=E(g)$width, edge.color="black")
```

It is important to note that, whenever we use iterators to assign new attribute values, the new values are recycled. So in the following example half of the vertices will be black, the other half red, in an alternated way.

```r
g <- graph.ring(10)
V(g)$color <- c("black", "red")
plot(g, layout=layout.circle)
```

For the recycling, the standard R rules apply and a warning is given if the number of items to replace is not a multiple of the replacement length. E.g. the following code gives a warning, because we set the attribute for three vertices, but supply only two values:

```r
g <- graph.tree(10)
V(g)$color <- "grey"
V(g)[1:3]$color <- c("green", "blue")
```

If a new vertex/edge attribute is created with an assignment, but only a subset of of vertices are specified, then the rest is set to `NA` if the new values are in a vector and to `NULL` if they are a list. Try the following:

```r
V(g)[5]$foo <- "foo"
V(g)$foo
V(g)[5]$bar <- list(bar="bar")
V(g)$bar
```
There are some special functions which are only defined in the indexing expressions of vertex and edge sequences. For vertex sequences these are: \texttt{nei}, \texttt{inc}, \texttt{from} and \texttt{to}, \texttt{innei} and \texttt{outnei}. (The \texttt{adj} special function is an alias for \texttt{inc}, for compatibility reasons.)

\texttt{nei} has a mandatory and an optional argument, the first is another vertex sequence, the second is a mode argument similar to that of the \texttt{neighbors} function. \texttt{nei} returns a logical vector of the same length as the indexed vertex sequence and evaluates to \texttt{TRUE} for those vertices only which have a neighbor vertex in the vertex sequence supplied as a parameter. Thus for selecting all neighbors of vertices 1 and 2 one can write:

\begin{verbatim}
V(g) [ nei( 1:2 ) ]
\end{verbatim}

The mode argument (just like for \texttt{neighbors}) gives the type of the neighbors to be included, it is interpreted only in directed graphs, and defaults to all types of neighbors. See the example below. \texttt{innei(v)} is a shorthand for the ‘incoming’ neighbors (\texttt{nei(v, mode="in")}), and \texttt{outnei(v)} is a shorthand for the ‘outgoing’ neighbors (\texttt{nei(v, mode="out")}).

\texttt{inc} takes an edge sequence as an argument and returns \texttt{TRUE} for vertices which have at least one incident edge in it.

\texttt{from} and \texttt{to} are similar to \texttt{inc} but only edges originated at (\texttt{from}) or pointing to (\texttt{to}) are taken into account.

For edge sequences the special functions are: \texttt{inc}, \texttt{from}, \texttt{to}, \%--\%, \%->\% and \%<-\%.

\texttt{inc} takes a vertex sequence as an argument and returns \texttt{TRUE} for edges which have an incident vertex in it.

\texttt{from} and \texttt{to} are similar to \texttt{inc}, but only vertices at the source (\texttt{from}) or target (\texttt{to}) of the edge.

The \%--\% operator selects edges connecting two vertex sequences, the direction of the edges is ignored. The \%->\% is different only for directed graphs and only edges pointing from the left hand side argument to the right hand side argument are selected. \%<-\% is exactly the opposite, it selects edges pointing from the right hand side to the left hand side.

\texttt{E} has two optional arguments: \texttt{P} and \texttt{path}. If given \texttt{P} can be used to select edges based on their end points, eg. \texttt{E(g, P=c(1,2))} selects edge 1->2.

\texttt{path} can be used to select all edges along a path. The path should be given with the visited vertex ids in the appropriate order.

See also the examples below.

\textbf{Note}

A note about the performance of the \texttt{V} and \texttt{E} functions, and the selection of edges and vertices. Since all selectors are evaluated as logical vectors on all vertices/edges, their performance is bad on large graphs. (Time complexity is proportional to the total number of vertices/edges.) We suggest using the \texttt{neighbors}, \texttt{incident} functions and simple R vector operations for manipulating vertex/edge sequences in large graphs.

system.time(incident(largeg, 1))

---

k.regular.game  Create a random regular graph
Description

Generate a random graph where each vertex has the same degree.

Usage

k.regular.game (no.of.nodes, k, directed = FALSE, multiple = FALSE)

Arguments

  no.of.nodes  Integer scalar, the number of vertices in the generated graph.
  k            Integer scalar, the degree of each vertex in the graph, or the out-degree and in-degree in a directed graph.
  directed    Logical scalar, whether to create a directed graph.
  multiple    Logical scalar, whether multiple edges are allowed.

Details

This game generates a directed or undirected random graph where the degrees of vertices are equal to a predefined constant k. For undirected graphs, at least one of k and the number of vertices must be even.

The game simply uses degree.sequence.game with appropriately constructed degree sequences.

Value

An igraph graph.

Author(s)

Tamas Nepusz <ntamas@gmail.com>

See Also

degree.sequence.game for a generator with prescribed degree sequence.

Examples

## A simple ring
ring <- k.regular.game(10, 2)
plot(ring)

## k-regular graphs on 10 vertices, with k=1:9
k10 <- lapply(1:9, k.regular.game, no.of.nodes=10)
layout(matrix(1:9, nrow=3, byrow=TRUE))
sapply(k10, plot, vertex.label=NA)
kleinberg

Kleinberg’s centrality scores.

Description

Kleinberg’s hub and authority scores.

Usage

authority.score (graph, scale = TRUE, weights=NULL, options = igraph.arpack.default)
hub.score (graph, scale = TRUE, weights=NULL, options = igraph.arpack.default)

Arguments

graph The input graph.
scale Logical scalar, whether to scale the result to have a maximum score of one. If no scaling is used then the result vector has unit length in the Euclidean norm.
weights Optional positive weight vector for calculating weighted scores. If the graph has a weight edge attribute, then this is used by default.
options A named list, to override some ARPACK options. See arpack for details.

Details

The authority scores of the vertices are defined as the principal eigenvector of \( A^T A \), where \( A \) is the adjacency matrix of the graph.

The hub scores of the vertices are defined as the principal eigenvector of \( AA^T \), where \( A \) is the adjacency matrix of the graph.

Obviously, for undirected matrices the adjacency matrix is symmetric and the two scores are the same.

Value

A named list with members:

vector The authority/hub scores of the vertices.
value The corresponding eigenvalue of the calculated principal eigenvector.
options Some information about the ARPACK computation, it has the same members as the options member returned by arpack, see that for documentation.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

Examples

```r
## An in-star
g <- graph.star(10)
hub.score(g)$vector
authority.score(g)$vector

## A ring
g2 <- graph.ring(10)
hub.score(g2)$vector
authority.score(g2)$vector
```

Description

This is a fast, nearly linear time algorithm for detecting community structure in networks. In works by labeling the vertices with unique labels and then updating the labels by majority voting in the neighborhood of the vertex.

Usage

```r
label.propagation.community (graph, weights = NULL,
  initial = NULL, fixed = NULL)
```

Arguments

- **graph**: The input graph, should be undirected to make sense.
- **weights**: An optional weight vector. It should contain a positive weight for all the edges. The ‘weight’ edge attribute is used if present. Supply ‘NA’ here if you want to ignore the ‘weight’ edge attribute.
- **initial**: The initial state. If NULL, every vertex will have a different label at the beginning. Otherwise it must be a vector with an entry for each vertex. Non-negative values denote different labels, negative entries denote vertices without labels.
- **fixed**: Logical vector denoting which labels are fixed. Of course this makes sense only if you provided an initial state, otherwise this element will be ignored. Also note that vertices without labels cannot be fixed.
Details

This function implements the community detection method described in: Raghavan, U.N. and Albert, R. and Kumara, S.: Near linear time algorithm to detect community structures in large-scale networks. Phys Rev E 76, 036106. (2007). This version extends the original method by the ability to take edge weights into consideration and also by allowing some labels to be fixed.

From the abstract of the paper: “In our algorithm every node is initialized with a unique label and at every step each node adopts the label that most of its neighbors currently have. In this iterative process densely connected groups of nodes form a consensus on a unique label to form communities.”

Value

label.propagation.community returns a communities object, please see the communities manual page for details.

Author(s)

Tamas Nepusz <ntamas@gmail.com> for the C implementation, Gabor Csardi <csardi.gabor@gmail.com> for this manual page.

References

Examples

g <- erdos.renyi.game(10, 5/10) #du% erdos.renyi.game(9, 5/9)
g <- add.edges(g, c(1, 12))
label.propagation.community(g)

layout

Generate coordinates for plotting graphs

Description

Some simple and not so simple functions determining the placement of the vertices for drawing a graph.
Usage

```
layout.auto(graph, dim=2, ...)
layout.random(graph, params, dim=2)
layout.circle(graph, params)
layout.sphere(graph, params)
layout.fruchterman.reingold(graph, ..., dim=2, params)
layout.kamada.kawai(graph, ..., dim=2, params)
layout.spring(graph, ..., params)
layout.reingold.tilford(graph, ..., params)
layout.fruchterman.reingold.grid(graph, ..., params)
layout.lgl(graph, ..., params)
layout.graphopt(graph, ..., params=list())
layout.svd(graph, d=shortest.paths(graph), ...)  # deprecated
layout.norm(layout, xmin = NULL, xmax = NULL, ymin = NULL, ymax = NULL,
            zmin = NULL, zmax = NULL)
```

Arguments

- **graph**
  The graph to place.
- **params**
  The list of function dependent parameters.
- **dim**
  Numeric constant, either 2 or 3. Some functions are able to generate 2d and 3d layouts as well, supply this argument to change the default behavior.
- **...**
  Function dependent parameters, this is an alternative notation to the `params` argument. For `layout.auto` these extra parameters are simply passed to the real layout function, if one is called.
- **d**
  The matrix used for singular value decomposition. By default it is the distance matrix of the graph.
- **layout**
  A matrix with two or three columns, the layout to normalize.
- **xmin, xmax**
  The limits for the first coordinate, if one of them or both are NULL then no normalization is performed along this direction.
- **ymin, ymax**
  The limits for the second coordinate, if one of them or both are NULL then no normalization is performed along this direction.
- **zmin, zmax**
  The limits for the third coordinate, if one of them or both are NULL then no normalization is performed along this direction.

Details

These functions calculate the coordinates of the vertices for a graph usually based on some optimality criterion.

`layout.auto` tries to choose an appropriate layout function for the supplied graph, and uses that to generate the layout. The current implementations works like this:

1. If the graph has a graph attribute called `layout`, then this is used. If this attribute is an R function, then it is called, with the graph and any other extra arguments.

2. Otherwise, if the graph has vertex attributes called `x` and `y`, then these are used as coordinates. If the graph has an additional `z` vertex attribute, that is also used.
3. Otherwise, if the graph is connected and has less than 100 vertices, the Kamada-Kawai layout is used, by calling `layout.kamada.kawai`.

4. Otherwise, if the graph has less than 1000 vertices, then the Fruchterman-Reingold layout is used, by calling `layout.fruchterman.reingold`.

5. Otherwise the DrL layout is used, `layout.drl` is called.

`layout.random` simply places the vertices randomly on a square. It has no parameters.

`layout.circle` places the vertices on a unit circle equidistantly. It has no parameters.

`layout.sphere` places the vertices (approximately) uniformly on the surface of a sphere, this is thus a 3d layout. It is not clear however what “uniformly on a sphere” means.

`layout.fruchterman.reingold` uses a force-based algorithm proposed by Fruchterman and Reingold, see references. Parameters and their default values:

- **niter** Numeric, the number of iterations to perform (500).
- **coolexp** Numeric, the cooling exponent for the simulated annealing (3).
- **maxdelta** Maximum change (`vcount(graph)`).
- **area** Area parameter (`vcount(graph)**2`).
- **repulserad** Cancellation radius (`area*vcount(graph)`).
- **weights** A vector giving edge weights or NULL. If not NULL then the attraction along the edges will be multiplied by the given edge weights (NULL).
- **minx** If not NULL, then it must be a numeric vector that gives lower boundaries for the ‘x’ coordinates of the vertices. The length of the vector must match the number of vertices in the graph.
- **maxx** Similar to **minx**, but gives the upper boundaries.
- **miny** Similar to **minx**, but gives the lower boundaries of the ‘y’ coordinates.
- **maxy** Similar to **minx**, but gives the upper boundaries of the ‘y’ coordinates.
- **minz** Similar to **minx**, but gives the lower boundaries of the ‘z’ coordinates, if the **dim** argument is 3. Otherwise it is ignored.
- **maxz** Similar to **minx**, but gives the upper boundaries of the ‘z’ coordinates, if the **dim** argument is 3. Otherwise it is ignored.
- **start** If given, then it should be a matrix with two columns and one line for each vertex. This matrix will be used as starting positions for the algorithm. If not given, then a random starting matrix is used.

This function was ported from the SNA package.

`layout.kamada.kawai` is another force based algorithm. Parameters and default values:

- **niter** Number of iterations to perform (1000).
- **sigma** Sets the base standard deviation of position change proposals (`vcount(graph)/4`).
- **initemp** The initial temperature (10).
- **coolexp** The cooling exponent (0.99).
- **kkconst** Sets the Kamada-Kawai vertex attraction constant (`vcount(graph)**2`).
**minx** If not NULL, then it must be a numeric vector that gives lower boundaries for the ‘x’ coordinates of the vertices. The length of the vector must match the number of vertices in the graph.

**maxx** Similar to minx, but gives the upper boundaries.

**miny** Similar to minx, but gives the lower boundaries of the ‘y’ coordinates.

**maxy** Similar to minx, but gives the upper boundaries of the ‘y’ coordinates.

**minz** Similar to minx, but gives the lower boundaries of the ‘z’ coordinates, if the dim argument is 3. Otherwise it is ignored.

**maxz** Similar to minx, but gives the upper boundaries of the ‘z’ coordinates, if the dim argument is 3. Otherwise it is ignored.

**start** If given, then it should be a matrix with two columns and one line for each vertex. This matrix will be used as starting positions for the algorithm. If not given, then a random starting matrix is used.

This function performs very well for connected graphs, but it gives poor results for unconnected ones. This function was ported from the SNA package.

**layout.spring** is a spring embedder algorithm. Parameters and default values:

**mass** The vertex mass (in ‘quasi-kilograms’). (Defaults to 0.1.)

**equil** The equilibrium spring extension (in ‘quasi-meters’). (Defaults to 1.)

**k** The spring coefficient (in ‘quasi-Newton per quasi-meter’). (Defaults to 0.001.)

**repeqdis** The point at which repulsion (if employed) balances out the spring extension force (in ‘quasi-meters’). (Defaults to 0.1.)

**kfr** The base coefficient of kinetic friction (in ‘quasi-Newton quasi-kilograms’). (Defaults to 0.01.)

**repulse** Should repulsion be used? (Defaults to FALSE.)

This function was ported from the SNA package.

**layout.reingold.tilford** generates a tree-like layout, so it is mainly for trees. Parameters and default values:

**root** The id of the root vertex, defaults to 1.

**circular** Logical scalar, whether to plot the tree in a circular fashion, defaults to FALSE.

**flip.y** Logical scalar, whether to flip the ‘y’ coordinates. The default is flipping because that puts the root vertex on the top.

**layout.fruchterman.reingold.grid** is similar to **layout.fruchterman.reingold** but repelling force is calculated only between vertices that are closer to each other than a limit, so it is faster. Parameters and default values:

**niter** Numeric, the number of iterations to perform (500).

**maxdelta** Maximum change for one vertex in one iteration. (The number of vertices in the graph.)

**area** The area of the surface on which the vertices are placed. (The square of the number of vertices.)

**coolexp** The cooling exponent of the simulated annealing (1.5).

**repulserad** Cancellation radius for the repulsion (the area times the number of vertices).
**cellsize** The size of the cells for the grid. When calculating the repulsion forces between vertices only vertices in the same or neighboring grid cells are taken into account (the fourth root of the number of area).

**start** If given, then it should be a matrix with two columns and one line for each vertex. This matrix will be used as starting positions for the algorithm. If not given, then a random starting matrix is used.

`layout.lgl` is for large connected graphs, it is similar to the layout generator of the Large Graph Layout software ([http://lgl.sourceforge.net/](http://lgl.sourceforge.net/)). Parameters and default values:

**maxiter** The maximum number of iterations to perform (150).

**maxdelta** The maximum change for a vertex during an iteration (the number of vertices).

**area** The area of the surface on which the vertices are placed (square of the number of vertices).

**coolexp** The cooling exponent of the simulated annealing (1.5).

**repulserad** Cancellation radius for the repulsion (the area times the number of vertices).

**cellsize** The size of the cells for the grid. When calculating the repulsion forces between vertices only vertices in the same or neighboring grid cells are taken into account (the fourth root of the number of area).

**root** The id of the vertex to place at the middle of the layout. The default value is -1 which means that a random vertex is selected.

`layout.graphopt` is a port of the graphopt layout algorithm by Michael Schmuhl. graphopt version 0.4.1 was rewritten in C and the support for layers was removed (might be added later) and a code was a bit reorganized to avoid some unnecessary steps is the node charge (see below) is zero.

graphopt uses physical analogies for defining attracting and repelling forces among the vertices and then the physical system is simulated until it reaches an equilibrium. (There is no simulated annealing or anything like that, so a stable fixed point is not guaranteed.)

See also [http://www.schmuhl.org/graphopt/](http://www.schmuhl.org/graphopt/) for the original graphopt.

Parameters and default values:

**niter** Integer scalar, the number of iterations to perform. Should be a couple of hundred in general. If you have a large graph then you might want to only do a few iterations and then check the result. If it is not good enough you can feed it in again in the **start** argument. The default value is 500.

**charge** The charge of the vertices, used to calculate electric repulsion. The default is 0.001.

**mass** The mass of the vertices, used for the spring forces. The default is 30.

**spring.length** The length of the springs, an integer number. The default value is zero.

**spring.constant** The spring constant, the default value is one.

**max_sa_movement** Real constant, it gives the maximum amount of movement allowed in a single step along a single axis. The default value is 5.

**start** If given, then it should be a matrix with two columns and one line for each vertex. This matrix will be used as starting positions for the algorithm. If not given, then a random starting matrix is used.
layout.svd is a currently experimental layout function based on singular value decomposition. It does not have the usual params argument, but take a single argument, the distance matrix of the graph. This function generates the layout separately for each graph component and then merges them via layout.merge.

layout.norm normalizes a layout, it linearly transforms each coordinate separately to fit into the given limits.

layout.drl is another force-driven layout generator, it is suitable for quite large graphs. See layout.drl for details.

Value

All these functions return a numeric matrix with at least two columns and the same number of lines as the number of vertices.

Examples

```r
# Fixing ego
minC <- rep(-Inf, vcount(g))
maxC <- rep(Inf, vcount(g))
minC[1] <- maxC[1] <- 0
co <- layout.fruchterman.reingold(g, minx=minC, maxx=maxC,
                                  miny=minC, maxy=maxC)
```

```r
# Not run: plot(g, layout=co, vertex.size=30, edge.arrow.size=0.2,
  vertex.label=c("ego", rep("", vcount(g)-1)), rescale=FALSE,
  xlab=range(co[,1]), ylab=range(co[,2]), vertex.label.dist=1,
  vertex.label.color="red")
axis(1)
```
**layout.bipartite**

- `axis(2)`

## Description

Minimize edge-crossings in a simple two-row (or column) layout for bipartite graphs.

## Usage

```r
layout.bipartite (graph, types = NULL, hgap = 1, vgap = 1, maxiter = 100)
```

## Arguments

- **graph**: The bipartite input graph. It should have a logical `type` vertex attribute, or the `types` argument must be given.
- **types**: A logical vector, the vertex types. If this argument is `NULL` (the default), then the `type` vertex attribute is used.
- **hgap**: Real scalar, the minimum horizontal gap between vertices in the same layer.
- **vgap**: Real scalar, the distance between the two layers.
- **maxiter**: Integer scalar, the maximum number of iterations in the crossing minimization stage. 100 is a reasonable default; if you feel that you have too many edge crossings, increase this.

## Details

The layout is created by first placing the vertices in two rows, according to their types. Then the positions within the rows are optimized to minimize edge crossings, using the Sugiyama algorithm (see `layout.sugiyama`).

## Value

A matrix with two columns and as many rows as the number of vertices in the input graph.

## Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

Examples

```r
# Random bipartite graph
inc <- matrix(sample(0:1, 50, replace=TRUE, prob=c(2,1)), 10, 5)
g <- graph.incidence(inc)
plot(g, layout=layout.bipartite,
    vertex.color=c("green","cyan")[V(g)$type+1])

# Two columns
lay <- layout.bipartite(g)
plot(g, layout=lay[,2:1])
```

Description

DrL is a force-directed graph layout toolbox focused on real-world large-scale graphs, developed by Shawn Martin and colleagues at Sandia National Laboratories.

Usage

```r
layout.drl (graph, use.seed = FALSE, seed = matrix(runif(vcount(graph) * 2), ncol = 2), options = igraph.drl.default, weights = E(graph)$weight, fixed = NULL, dim = 2)
```

Arguments

- **graph**: The input graph, in can be directed or undirected.
- **use.seed**: Logical scalar, whether to use the coordinates given in the seed argument as a starting point.
- **seed**: A matrix with two columns, the starting coordinates for the vertices is use.seed is TRUE. It is ignored otherwise.
- **options**: Options for the layout generator, a named list. See details below.
- **weights**: Optional edge weights. Supply NULL here if you want to weight edges equally. By default the weight edge attribute is used if the graph has one.
- **fixed**: Logical vector, it can be used to fix some vertices. All vertices for which it is TRUE are kept at the coordinates supplied in the seed matrix. It is ignored it NULL or if use.seed is FALSE.
- **dim**: Either ‘2’ or ‘3’, it specifies whether we want a two dimensional or a three dimensional layout. Note that because of the nature of the DrL algorithm, the three dimensional layout takes significantly longer to compute.
Details

This function implements the force-directed DrL layout generator.

The generator has the following parameters:

- **edge.cut** Edge cutting is done in the late stages of the algorithm in order to achieve less dense layouts. Edges are cut if there is a lot of stress on them (a large value in the objective function sum). The edge cutting parameter is a value between 0 and 1 with 0 representing no edge cutting and 1 representing maximal edge cutting.

- **init.iterations** Number of iterations in the first phase.

- **init.temperature** Start temperature, first phase.

- **init.attraction** Attraction, first phase.

- **init.damping.mult** Damping, first phase.

- **liquid.iterations** Number of iterations, liquid phase.

- **liquid.temperature** Start temperature, liquid phase.

- **liquid.attraction** Attraction, liquid phase.

- **liquid.damping.mult** Damping, liquid phase.

- **expansion.iterations** Number of iterations, expansion phase.

- **expansion.temperature** Start temperature, expansion phase.

- **expansion.attraction** Attraction, expansion phase.

- **expansion.damping.mult** Damping, expansion phase.

- **cooldown.iterations** Number of iterations, cooldown phase.

- **cooldown.temperature** Start temperature, cooldown phase.

- **cooldown.attraction** Attraction, cooldown phase.

- **cooldown.damping.mult** Damping, cooldown phase.

- **crunch.iterations** Number of iterations, crunch phase.

- **crunch.temperature** Start temperature, crunch phase.

- **crunch.attraction** Attraction, crunch phase.

- **crunch.damping.mult** Damping, crunch phase.

- **simmer.iterations** Number of iterations, simmer phase.

- **simmer.temperature** Start temperature, simmer phase.

- **simmer.attraction** Attraction, simmer phase.

- **simmer.damping.mult** Damping, simmer phase.

There are five pre-defined parameter settings as well, these are called igraph.drl.default, igraph.drl.coarsen, igraph.drl.coarsest, igraph.drl.refine and igraph.drl.final.

Value

A numeric matrix with two columns.
layout.grid

Simple grid layout

Description

This layout places vertices on a rectangular grid, in two or three dimensions.

Usage

layout.grid (graph, width = 0)
layout.grid.3d (graph, width = 0, height = 0)

Arguments

graph The input graph.
width The number of vertices in a single row of the grid. If this is zero or negative for layout.grid, then the width of the grid will be the square root of the number of vertices in the graph, rounded up to the next integer. Similarly, it will be the cube root for layout.grid.3d.
height The number of vertices in a single column of the grid, for three dimensional layouts. If this is zero or negative, then it is determined automatically.

Details

These functions place the vertices on a simple rectangular grid, one after the other. If you want to change the order of the vertices, then see the permute.vertices function.
Value

A two-column matrix for `layout.grid`, a three-column matrix for `layout.grid.3d`.

## Not run:
plot(g, layout=layout.grid)
grlplot(g, layout=layout.grid.3d)

## End(Not run)
```

### layout.mds

**Graph layout by multidimensional scaling**

Description

Multidimensional scaling of some distance matrix defined on the vertices of a graph.

Usage

```r
layout.mds(graph, dist=NULL, dim=2, options=igraph.arpack.default)
```

Arguments

- **graph**: The input graph.
- **dist**: The distance matrix for the multidimensional scaling. If `NULL` (the default), then the unweighted shortest path matrix is used.
- **dim**: `layout.mds` supports dimensions up to the number of nodes minus one, but only if the graph is connected; for unconnected graphs, the only possible values is 2. This is because `layout.merge` only works in 2D.
- **options**: This is currently ignored, as ARPACK is not used any more for solving the eigenproblem.
Details

`layout.mds` uses metric multidimensional scaling for generating the coordinates. Multidimensional scaling aims to place points from a higher dimensional space in a (typically) 2 dimensional plane, so that the distance between the points are kept as much as this is possible.

By default igraph uses the shortest path matrix as the distances between the nodes, but the user can override this via the `dist` argument.

This function generates the layout separately for each graph component and then merges them via `layout.merge`.

Value

A numeric matrix with `dim` columns.

```

layout.merge  Merging graph layouts

Description

Place several graphs on the same layout

Usage

```r
  layout.merge(graphs, layouts, method = "dla")
  piecewise.layout(graph, layout=layout.kamada.kawai, ...)
```
Arguments

graphs  A list of graph objects.
layouts  A list of two-column matrices.
method  Character constant giving the method to use. Right now only dla is implemented.
graph  The input graph.
layout  A function object, the layout function to use.
...  Additional arguments to pass to the layout layout function.

Details

layout.merge takes a list of graphs and a list of coordinates and places the graphs in a common layout. The method to use is chosen via the method parameter, although right now only the dla method is implemented.

The dla method covers the graph with circles. Then it sorts the graphs based on the number of vertices first and places the largest graph at the center of the layout. Then the other graphs are placed in decreasing order via a DLA (diffusion limited aggregation) algorithm: the graph is placed randomly on a circle far away from the center and a random walk is conducted until the graph walks into the larger graphs already placed or walks too far from the center of the layout.

The piecewise.layout function disassembles the graph first into maximal connected components and calls the supplied layout function for each component separately. Finally it merges the layouts via calling layout.merge.

Value

A matrix with two columns and as many lines as the total number of vertices in the graphs.

# create 20 scale-free graphs and place them in a common layout
graphs <- lapply(sample(5:20, 20, replace=TRUE),
                 barabasi.game, directed=FALSE)
layouts <- lapply(graphs, layout.kamada.kawai)
lay <- layout.merge(graphs, layouts)
g <- graph.disjoint.union(graphs)
## Not run: plot(g, layout=lay, vertex.size=3, labels=NA, edge.color="black")
```
layout.star  

Generate coordinates to place the vertices of a graph in a star-shape

Description

A simple layout generator, that places one vertex in the center of a circle and the rest of the vertices equidistantly on the perimeter.

Usage

layout.star(graph, center = V(graph)[1], order = NULL)

Arguments

- graph: The graph to layout.
- center: The id of the vertex to put in the center. By default it is the first vertex.
- order: Numeric vector, the order of the vertices along the perimeter. The default ordering is given by the vertex ids.

Details

It is possible to choose the vertex that will be in the center, and the order of the vertices can be also given.

Value

A matrix with two columns and as many rows as the number of vertices in the input graph.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

layout.star(g)
```
The Sugiyama graph layout generator

Description

Sugiyama layout algorithm for layered directed acyclic graphs. The algorithm minimized edge crossings.

Usage

layout.sugiyama (graph, layers = NULL, hgap = 1, vgap = 1, maxiter = 100,
weights = NULL, attributes = c("default", "all", "none"))

Arguments

- **graph**: The input graph.
- **layers**: A numeric vector or NULL. If not NULL, then it should specify the layer index of the vertices. Layers are numbered from one. If NULL, then igraph calculates the layers automatically.
- **hgap**: Real scalar, the minimum horizontal gap between vertices in the same layer.
- **vgap**: Real scalar, the distance between layers.
- **maxiter**: Integer scalar, the maximum number of iterations in the crossing minimization stage. 100 is a reasonable default; if you feel that you have too many edge crossings, increase this.
- **weights**: Optional edge weight vector. If NULL, then the 'weight' edge attribute is used, if there is one. Supply `NA` here and igraph ignores the edge weights.
- **attributes**: Which graph/vertex/edge attributes to keep in the extended graph. 'default' keeps the 'size', 'size2', 'shape', 'label' and 'color' vertex attributes and the 'arrow.mode' and 'arrow.size' edge attributes. 'all' keep all graph, vertex and edge attributes, 'none' keeps none of them.

Details

This layout algorithm is designed for directed acyclic graphs where each vertex is assigned to a layer. Layers are indexed from zero, and vertices of the same layer will be placed on the same horizontal line. The X coordinates of vertices within each layer are decided by the heuristic proposed by Sugiyama et al. to minimize edge crossings.

You can also try to lay out undirected graphs, graphs containing cycles, or graphs without an a priori layered assignment with this algorithm. igraph will try to eliminate cycles and assign vertices to layers, but there is no guarantee on the quality of the layout in such cases.

The Sugiyama layout may introduce “bends” on the edges in order to obtain a visually more pleasing layout. This is achieved by adding dummy nodes to edges spanning more than one layer. The resulting layout assigns coordinates not only to the nodes of the original graph but also to the dummy nodes. The layout algorithm will also return the extended graph with the dummy nodes.

For more details, see the reference below.
Value

A list with the components:

- **layout**: The layout, a two-column matrix, for the original graph vertices.
- **layout.dummy**: The layout for the dummy vertices, a two-column matrix.
- **extd_graph**: The original graph, extended with dummy vertices. The ‘dummy’ vertex attribute is set on this graph, it is a logical attribute, and it tells you whether the vertex is a dummy vertex. The ‘layout’ graph attribute is also set, and it is the layout matrix for all (original and dummy) vertices.

leading.eigenvector.community

Community structure detecting based on the leading eigenvector of the community matrix

Description

This function tries to find densely connected subgraphs in a graph by calculating the leading non-negative eigenvector of the modularity matrix of the graph.

Usage

leading.eigenvector.community(graph, steps = -1, weights = NULL, start = NULL, options = igraph.arpack.default, callback = NULL, extra = NULL, env = parent.frame())

community.le.to.membership(merges, steps, membership)
Arguments

- **graph**
  The input graph. Should be undirected as the method needs a symmetric matrix.

- **steps**
  The number of steps to take, this is actually the number of tries to make a step.
  It is not a particularly useful parameter.
  For `community::leading.eigenvector.community` the number of merges to produce from the supplied `membership` vector.

- **weights**
  An optional weight vector. The ‘weight’ edge attribute is used if present. Supply ‘NA’ here if you want to ignore the ‘weight’ edge attribute.

- **start**
  NULL, or a numeric membership vector, giving the start configuration of the algorithm.

- **membership**
  The starting community structure on which `steps` merges are performed.

- **options**
  A named list to override some ARPACK options.

- **callback**
  If not NULL, then it must be callback function. This is called after each iteration, after calculating the leading eigenvector of the modularity matrix. See details below.

- **extra**
  Additional argument to supply to the callback function.

- **env**
  The environment in which the callback function is evaluated.

- **merges**
  The merge matrix, possible from the result of `community::leading.eigenvector.community`.

Details

The function documented in these sections implements the ‘leading eigenvector’ method developed by Mark Newman, see the reference below.

The heart of the method is the definition of the modularity matrix, $B$, which is $B=A-P$, $A$ being the adjacency matrix of the (undirected) network, and $P$ contains the probability that certain edges are present according to the ‘configuration model’. In other words, a $P_{ij}$ element of $P$ is the probability that there is an edge between vertices $i$ and $j$ in a random network in which the degrees of all vertices are the same as in the input graph.

The leading eigenvector method works by calculating the eigenvector of the modularity matrix for the largest positive eigenvalue and then separating vertices into two community based on the sign of the corresponding element in the eigenvector. If all elements in the eigenvector are of the same sign that means that the network has no underlying community structure. Check Newman’s paper to understand why this is a good method for detecting community structure.

`community::leading.eigenvector.community` creates a membership vector from the result of `leading.eigenvector.community`. It takes `membership` and permforms `steps` merges, according to the supplied `merges` matrix.

Value

`leading.eigenvector.community` returns a named list with the following members:

- **membership**
  The membership vector at the end of the algorithm, when no more splits are possible.

- **merges**
  The merges matrix starting from the state described by the `membership` member.
  This is a two-column matrix and each line describes a merge of two communities, the first line is the first merge and it creates community ‘N’, $N$ is the number of initial communities in the graph, the second line creates community $N+1$, etc.
options Information about the underlying ARPACK computation, see arpack for details.

community.le.to.membership returns a named list with two components:

membership A membership vector, a numerical vector indication which vertex belongs to
which community. The communities are always numbered from one.

csize A numeric vector giving the sizes of the communities.

Callback functions

The callback argument can be used to supply a function that is called after each eigenvector
calculation. The following arguments are supplied to this function:

membership The actual membership vector, with zero-based indexing.

community The community that the algorithm just tried to split, community numbering starts with
zero here.

value The eigenvalue belonging to the leading eigenvector the algorithm just found.

vector The leading eigenvector the algorithm just found.

multiplier An R function that can be used to multiple the actual modularity matrix with an arbitrary
vector. Supply the vector as an argument to perform this multiplication. This function can be
used with ARPACK.

extra The extra argument that was passed to leading.eigenvector.community.

lec <- leading.eigenvector.community(g)
lec

leading.eigenvector.community(g, start=membership(lec))
Description
This function calculates the line graph of another graph.

Usage
line.graph(graph)

Arguments
graph The input graph, it can be directed or undirected.

Details
The line graph $L(G)$ of a $G$ undirected graph is defined as follows. $L(G)$ has one vertex for each edge in $G$ and two vertices in $L(G)$ are connected by an edge if their corresponding edges share an end point.

The line graph $L(G)$ of a $G$ directed graph is slightly different, $L(G)$ has one vertex for each edge in $G$ and two vertices in $L(G)$ are connected by a directed edge if the target of the first vertex’s corresponding edge is the same as the source of the second vertex’s corresponding edge.

Value
A new graph object.

Author(s)
Gabor Csardi <csardi.gabor@gmail.com>, the first version of the C code was written by Vincent Matossian.

Examples
# generate the first De-Bruijn graphs
g <- graph.full(2, directed=TRUE, loops=TRUE)
line.graph(g)
line.graph(line.graph(g))
line.graph(line.graph(line.graph(g)))
Description

Maximum cardinality search is a simple ordering a vertices that is useful in determining the chordality of a graph.

Usage

maximum.cardinality.search(graph)

Arguments

graph  The input graph. It may be directed, but edge directions are ignored, as the algorithm is defined for undirected graphs.

Details

Maximum cardinality search visits the vertices in such an order that every time the vertex with the most already visited neighbors is visited. Ties are broken randomly.

The algorithm provides a simple basis for deciding whether a graph is chordal, see References below, and also is.chordal.

Value

A list with two components:

alpha  Numeric vector. The vertices ordered according to the maximum cardinality search.

alpham1  Numeric vector. The inverse of alpha.

### minimal.st.separators  
**Minimum size vertex separators**

**Description**

List all vertex sets that are minimal (s,t) separators for some s and t, in an undirected graph.

**Usage**

```r
minimal.st.separators(graph)
```

**Arguments**

- `graph`  
The input graph. It may be directed, but edge directions are ignored.

**Details**

A \((s, t)\) vertex separator is a set of vertices, such that after their removal from the graph, there is no path between \(s\) and \(t\) in the graph.

A \((s, t)\) vertex separator is minimal if none of its subsets is an \((s, t)\) vertex separator.

**Value**

A list of numeric vectors. Each vector contains a vertex set (defined by vertex ids), each vector is an \((s, t)\) separator of the input graph, for some \(s\) and \(t\).

**Author(s)**

Gabor Csardi &lt;csardi.gabor@gmail.com&gt;

**References**

Anne Berry, Jean-Paul Bordat and Olivier Cogis: Generating All the Minimal Separators of a Graph, In: Peter Widmayer, Gabriele Neyer and Stephan Eidenbenz (editors): *Graph-theoretic concepts in computer science*, 1665, 167–172, 1999. Springer.
Examples

```r
ring <- graph.ring(4)
minimal.st.separators(ring)

chvatal <- graph.famous("chvatal")
minimal.st.separators(chvatal)
```

---

**minimum.size.separators**

*Minimum size vertex separators*

**Description**

Find all vertex sets of minimal size whose removal separates the graph into more components.

**Usage**

```r
minimum.size.separators(graph)
```

**Arguments**

- `graph`: The input graph. It may be directed, but edge directions are ignored.

**Details**

This function implements the Kanevsky algorithm for finding all minimal-size vertex separators in an undirected graph. See the reference below for the details.

In the special case of a fully connected input graph with \( n \) vertices, all subsets of size \( n - 1 \) are listed as the result.

**Value**

A list of numeric vectors. Each numeric vector is a vertex separator.

lapply(minimum.size.separators(camp), function(x) V(camp)[x])

Description

A subgraph of a connected graph is a minimum spanning tree if it is tree, and the sum of its edge weights are the minimal among all tree subgraphs of the graph. A minimum spanning forest of a graph is the graph consisting of the minimum spanning trees of its components.
Usage

minimum.spanning.tree(graph, weights=NULL, algorithm=NULL, ...)

Arguments

graph  The graph object to analyze.
weights Numeric algorithm giving the weights of the edges in the graph. The order is determined by the edge ids. This is ignored if the unweighted algorithm is chosen.
algorithm The algorithm to use for calculation. unweighted can be used for unweighted graphs, and prim runs Prim’s algorithm for weighted graphs. If this is NULL then igraph tries to select the algorithm automatically: if the graph has an edge attribute called weight of the weights argument is not NULL then Prim’s algorithm is chosen, otherwise the unweighted algorithm is performed.

... Additional arguments, unused.

Details

If the graph is unconnected a minimum spanning forest is returned.

Value

A graph object with the minimum spanning forest. (To check that it is a tree check that the number of its edges is vcount(graph)-1.) The edge and vertex attributes of the original graph are preserved in the result.

```
modularity

Modularity of a community structure of a graph

Description

This function calculates how modular is a given division of a graph into subgraphs.

Usage

```
## S3 method for class 'igraph'
modularity(x, membership, weights = NULL, ...)
mod.matrix (graph, membership, weights = NULL)
```

Arguments

- `x,graph` The input graph.
- `membership` Numeric vector, for each vertex it gives its community. The communities are numbered from one.
- `weights` If not `NULL` then a numeric vector giving edge weights.
- `...` Additional arguments, none currently.

Details

`modularity` calculates the modularity of a graph with respect to the given `membership` vector.

The modularity of a graph with respect to some division (or vertex types) measures how good the division is, or how separated are the different vertex types from each other. It defined as

\[
Q = \frac{1}{2m} \sum_{i,j} (A_{ij} - \frac{k_i k_j}{2m}) \delta(c_i, c_j),
\]

where \( m \) is the number of edges, \( A_{ij} \) is the element of the adjacency matrix in row \( i \) and column \( j \), \( k_i \) is the degree of \( i \), \( k_j \) is the degree of \( j \), \( c_i \) is the type (or component) of \( i \), \( c_j \) that of \( j \), the sum goes over all \( i \) and \( j \) pairs of vertices, and \( \delta(x, y) \) is 1 if \( x = y \) and 0 otherwise.

If edge weights are given, then these are considered as the element of the adjacency matrix, and \( k_i \) is the sum of weights of adjacent edges for vertex \( i \).

`mod.matrix` calculates the modularity matrix. This is a dense matrix, and it is defined as the difference of the adjacency matrix and the configuration model null model matrix. In other words, element \( M_{ij} \) is given as \( A_{ij} - \frac{d_i d_j}{2m} \), where \( A_{ij} \) is the (possibly weighted) adjacency matrix, \( d_i \) is the degree of vertex \( i \), and \( m \) is the number of edges (or the total weights in the graph, if it is weighted).

Value

For `modularity` a numeric scalar, the modularity score of the given configuration.

For `mod.matrix` a numeric square matrix, its order is the number of vertices in the graph.

```

## multilevel.community

Finding community structure by multi-level optimization of modularity

### Description

This function implements the multi-level modularity optimization algorithm for finding community structure, see references below. It is based on the modularity measure and a hierarchial approach.

### Usage

```r
multilevel.community (graph, weights = NULL)
```

### Arguments

- **graph**: The input graph.
- **weights**: Optional positive weight vector. If the graph has a weight edge attribute, then this is used by default. Supply NA here if the graph has a weight edge attribute, but you want to ignore it.

### Details

It is based on the modularity measure and a hierarchial approach. Initially, each vertex is assigned to a community on its own. In every step, vertices are re-assigned to communities in a local, greedy approach.
way: each vertex is moved to the community with which it achieves the highest contribution to modularity. When no vertices can be reassigned, each community is considered a vertex on its own, and the process starts again with the merged communities. The process stops when there is only a single vertex left or when the modularity cannot be increased any more in a step.

This function was contributed by Tom Gregorovic.

Value

multilevel.community returns a communities object, please see the communities manual page for details.

Author(s)

Tom Gregorovic, Tamas Nepusz <ntamas@gmail.com>

Examples

# This is so simple that we will have only one level
g <- graph.full(5) %du% graph.full(5) %du% graph.full(5)
g <- add.edges(g, c(1, 6, 1, 11, 6, 11))
multilevel.community(g)

----------------

neighborhood Neighborhood of graph vertices

Description

These functions find the vertices not farther than a given limit from another fixed vertex, these are called the neighborhood of the vertex.

Usage

neighborhood.size(graph, order, nodes=V(graph), mode=c("all", "out", "in"))
neighborhood(graph, order, nodes=V(graph), mode=c("all", "out", "in"))
graph.neighborhood(graph, order, nodes=V(graph), mode=c("all", "out", "in"))
connect.neighborhood(graph, order, mode=c("all", "out", "in", "total"))
Arguments

- **graph**: The input graph.
- **order**: Integer giving the order of the neighborhood.
- **nodes**: The vertices for which the calculation is performed.
- **mode**: Character constant, it specifies how to use the direction of the edges if a directed graph is analyzed. For ‘out’ only the outgoing edges are followed, so all vertices reachable from the source vertex in at most `order` steps are counted. For ‘”in”’ all vertices from which the source vertex is reachable in at most `order` steps are counted. ‘”all”’ ignores the direction of the edges. This argument is ignored for undirected graphs.

Details

The neighborhood of a given order `o` of a vertex `v` includes all vertices which are closer to `v` than the order. I.e. order 0 is always `v` itself, order 1 is `v` plus its immediate neighbors, order 2 is order 1 plus the immediate neighbors of the vertices in order 1, etc.

- `neighborhood.size` calculates the size of the neighborhoods for the given vertices with the given order.
- `neighborhood` calculates the neighborhoods of the given vertices with the given order parameter.
- `graph.neighborhood` is creates (sub)graphs from all neighborhoods of the given vertices with the given order parameter. This function preserves the vertex, edge and graph attributes.
- `connect.neighborhood` creates a new graph by connecting each vertex to all other vertices in its neighborhood.

Value

- `neighborhood.size` returns with an integer vector.
- `neighborhood` returns with a list of integer vectors.
- `graph.neighborhood` returns with a list of graphs.
- `connect.neighborhood` returns with a new graph object.

Author(s)

Gabor Csardi `<csardi.gabor@gmail.com>`, the first version was done by Vincent Matossian

Examples

```r
g <- graph.ring(10)
neighborhood.size(g, 0, 1:3)
neighborhood.size(g, 1, 1:3)
neighborhood.size(g, 2, 1:3)
neighborhood(g, 0, 1:3)
neighborhood(g, 1, 1:3)
neighborhood(g, 2, 1:3)

# attributes are preserved
```
nexus

Query and download from the Nexus network repository

Description

The Nexus network repository is an online collection of network data sets. These functions can be used to query it and download data from it, directly as an igraph graph.

Usage

nexus.list(tags=NULL, offset=0, limit=10,
          operator=c("or", "and"),
          order=c("date", "name", "popularity"),
          nexus.url=getIgraphOpt("nexus.url"))

nexus.info(id, nexus.url=getIgraphOpt("nexus.url"))

nexus.get(id, offset=0, order=c("date", "name", "popularity"),
          nexus.url=getIgraphOpt("nexus.url"))

nexus.search(q, offset=0, limit=10,
             order=c("date", "name", "popularity"),
             nexus.url=getIgraphOpt("nexus.url"))

## S3 method for class 'nexusDatasetInfo'
print(x, ...)

## S3 method for class 'nexusDatasetInfoList'
summary(object, ...)

## S3 method for class 'nexusDatasetInfoList'
print(x, ...)

Arguments

tags A character vector, the tags that are searched. If not given (or NULL), then all datasets are listed.

offset An offset to select part of the results. Results are listed from offset+1.

limit The maximum number of results to return.

operator A character scalar. If 'or' (the default), then all datasets that have at least one of the given tags, are returned. If it if 'and', then only datasets that have all the given tags, are returned.

order The ordering of the results, possible values are: 'date', 'name', 'popularity'.

V(g)$name <- c("a", "b", "c", "d", "e", "f", "g", "h", "i", "j")

graph.neighborhood(g, 2, 1:3)

# connecting to the neighborhood

g <- graph.union(g, 10)
g <- connect.neighborhood(g, 2)

nexus
id  The numeric or character id of the data set to query or download. Instead of the
data set ids, it is possible to supply a `nexusDatasetInfo` or `nexusDatasetInfoList`
object here directly and then the query is done on the corresponding data set(s).

q  Nexus search string. See examples below. For the complete documentation
please see the Nexus homepage at [http://nexus.igraph.org](http://nexus.igraph.org).

nexus.url  The URL of the Nexus server. Don’t change this from the default, unless you
set up your own Nexus server.

x, object  The `nexusDatasetInfo` object to print.

...  Currently ignored.

Details

Nexus is an online repository of networks, with an API that allow programatic queries against it,
and programatic data download as well.

The `nexus.list` and `nexus.info` functions query the online database. They both return `nexusDatasetInfo`
objects. `nexus.info` returns more information than `nexus.list`.

`nexus.search` searches Nexus, and returns a list of data sets, as `nexusDatasetInfo` objects. See
below for some search examples.

`nexus.get` downloads a data set from Nexus, based on its numeric id, or based on a Nexus search
string. For search strings, only the first search hit is downloaded, but see also the `offset` argument.
(If there are not data sets found, then the function returns an error.)

The `nexusDatasetInfo` objects returned by `nexus.list` have the following fields:

id  The numeric id of the dataset.

sid  The character id of the dataset.

name  Character scalar, the name of the dataset.

vertices/edges  Character, the number of vertices and edges in the graph(s). Vertices and edges are
separated by a slash, and if the data set consists of multiple networks, then they are separated
by spaces.

tags  Character vector, the tags of the dataset. Directed graph have the tags ‘directed’. Undirected
graphs are tagged as ‘undirected’. Other common tags are: ‘weighted’, ‘bipartite’, ‘social
network’, etc.

networks  The ids and names of the networks in the data set. The numeric and character id are
separated by a slash, and multiple networks are separated by spaces.

`nexusDatasetInfo` objects returned by `nexus.info` have the following additional fields:

date  Character scalar, e.g. ‘2011-01-09’, the date when the dataset was added to the database.

formats  Character vector, the data formats in which the data set is available. The various formats
are separated by semicolons.

licence  Character scalar, the licence of the dataset.

licence url  Character scalar, the URL of the licence of the dataset. Please make sure you consult
this before using a dataset.

summary  Character scalar, the short description of the dataset, this is usually a single sentence.
**description** Character scalar, the full description of the dataset.

**citation** Character scalar, the paper(s) describing the dataset. Please cite these papers if you are using the dataset in your research, the licence of most datasets requires this.

**attributes** A list of lists, each list entry is a graph, vertex or edge attribute and has the following entries:

- **type** Type of the attribute, either 'graph', 'vertex' or 'edge'.
- **datatype** Data type of the attribute, currently it can be 'numeric' and 'string'.
- **name** Character scalar, the name of the attribute.
- **description** Character scalar, the description of the attribute.

The results of the Nexus queries are printed to the screen in a concise format, similar to the format of igraph graphs. A data set list (typically the result of `nexusNlist` and `nexusNsearch`) looks like this:

```
NEXUS 1-5/18 -- data set list
[1] kaptail.4  39/109-223  #18 Kapferer tailor shop
[2] condmatcollab2003  31163/120029  #17 Condensed matter collaborations+
[3] condmatcollab  16726/47594  #16 Condensed matter collaborations+
[4] powergrid  4941/6594  #15 Western US power grid
[5] celegansneural  297/2359  #14 C. Elegans neural network
```

Each line here represents a data set, and the following information is given about them: the character id of the data set (e.g. `kaptail` or `powergrid`), the number of vertices and number of edges in the graph of the data sets. For data sets with multiple graphs, intervals are given here. Then the numeric id of the data set and the remaining space is filled with the name of the data set.

Summary information about an individual Nexus data set is printed as

```
NEXUS B----  39 109-223 #18 kaptail -- Kapferer tailor shop
+ tags: directed; social network; undirected
+ nets: 1/KAPFTI2; 2/KAPFTS2; 3/KAPFTI1; 4/KAPFTS1
```

This is very similar to the header that is used for printing igraph graphs, but there are some differences as well. The four characters after the `NEXUS` word give the most important properties of the graph(s): the first is ‘U’ for undirected and ‘D’ for directed graphs, and ‘B’ if the data set contains both directed and undirected graphs. The second is ‘N’ named graphs. The third character is ‘W’ for weighted graphs, the fourth is ‘B’ if the data set contains bipartite graphs. Then the number of vertices and number of edges are printed, for data sets with multiple graphs, the smallest and the largest values are given. Then comes the numeric id, and the string id of the data set. The end of the first line contains the name of the data set. The second row lists the data set tags, and the third row the networks that are included in the data set.

Detailed data set information is printed similarly, but it contains more fields.

**Value**

`nexus.list` and `nexus.search` return a list of `nexusDatasetInfo` objects. The list also has these attributes:

- **size** The number of data sets returned by the query.
optimal.community

**totalsize**  The total number of data sets found for the query.

**offset**  The offset parameter of the query.

**limit**  The limit parameter of the query.

nexus.info returns a single nexusDatasetInfo object.

nexus.get returns an igraph graph object, or a list of graph objects, if the data set consists of multiple networks.

### optimal.community

*Optimal community structure*

**Description**

This function calculates the optimal community structure of a graph, by maximizing the modularity measure over all possible partitions.

**Usage**

```r
optimal.community(graph, weights = NULL)
```
Arguments

- **graph**: The input graph. Edge directions are ignored for directed graphs.
- **weights**: Optional positive weight vector for optimizing weighted modularity. If the graph has a weight edge attribute, then this is used by default. Supply NA to ignore the weights of a weighted graph.

Details

This function calculates the optimal community structure for a graph, in terms of maximal modularity score.

The calculation is done by transforming the modularity maximization into an integer programming problem, and then calling the GLPK library to solve that. Please the reference below for details.

Note that modularity optimization is an NP-complete problem, and all known algorithms for it have exponential time complexity. This means that you probably don’t want to run this function on larger graphs. Graphs with up to fifty vertices should be fine, graphs with a couple of hundred vertices might be possible.

Value

`optimal.community` returns a `communities` object, please see the `communities` manual page for details.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

References

See Also

`communities` for the documentation of the result, `modularity`. See also `fastgreedy.community` for a fast greedy optimizer.

Examples

```r
# Zachary's karate club
g <- graph.famous("Zachary")

# We put everything into a big 'try' block, in case
# igraph was compiled without GLPK support

try({
    # The calculation only takes a couple of seconds
    oc <- optimal.community(g)
})
```
## The Page Rank algorithm

### Description

Calculates the Google PageRank for the specified vertices.

### Usage

```r
page.rank (graph, algo = c("prpack", "arpack", "power"),
  vids = V(graph), directed = TRUE, damping = 0.85,
  personalized = NULL, weights = NULL, options = NULL)
```

```r
page.rank.old (graph, vids = V(graph), directed = TRUE, niter = 1000,
  eps = 0.001, damping = 0.85, old = FALSE)
```

### Arguments

- **graph**: The graph object.
- **algo**: Character scalar, which implementation to use to carry out the calculation. The default is "prpack", which uses the PRPACK library (https://github.com/dgleich/prpack). This is a new implementation in igraph version 0.7, and the suggested one, as it is the most stable and the fastest for all but small graphs. "arpack" uses the ARPACK library, the default implementation from igraph version 0.5 until version 0.7. "power" uses a simple implementation of the power method, this was the default in igraph before version 0.5 and is the same as calling page.rank.old.
- ** vids**: The vertices of interest.
- ** directed**: Logical, if true directed paths will be considered for directed graphs. It is ignored for undirected graphs.
- ** damping**: The damping factor ("d" in the original paper).
- ** personalized**: Optional vector giving a probability distribution to calculate personalized PageRank. For personalized PageRank, the probability of jumping to a node when abandoning the random walk is not uniform, but it is given by this vector. The vector should contain an entry for each vertex and it will be rescaled to sum up to one.
weights A numerical vector or NULL. This argument can be used to give edge weights for calculating the weighted PageRank of vertices. If this is NULL and the graph has a weight edge attribute then that is used. If weights is a numerical vector then it used, even if the graph has a weights edge attribute. If this is NA, then no edge weights are used (even if the graph has a weight edge attribute).

options Either a named list, to override some ARPACK options. See arpack for details; or a named list to override the default options for the power method (if algo="power"). The default options for the power method are niter=1000 and eps=0.001. This argument is ignored if the PRPACK implementation is used.

niter The maximum number of iterations to perform.

eps The algorithm will consider the calculation as complete if the difference of PageRank values between iterations change less than this value for every node.

old A logical scalar, whether the old style (pre igraph 0.5) normalization to use. See details below.

Details

For the explanation of the PageRank algorithm, see the following webpage: http://infolab.stanford.edu/~backrub/google.html, or the following reference:

igraph 0.5 (and later) contains two PageRank calculation implementations. The page.rank function uses ARPACK to perform the calculation, see also arpack.

The page.rank.old function performs a simple power method, this is the implementation that was available under the name page.rank in pre 0.5 igraph versions. Note that page.rank.old has an argument called old. If this argument is FALSE (the default), then the proper PageRank algorithm is used, i.e. \((1 - d)/n\) is added to the weighted PageRank of vertices to calculate the next iteration. If this argument is TRUE then \((1 - d)\) is added, just like in the PageRank paper; \(d\) is the damping factor, and \(n\) is the total number of vertices. A further difference is that the old implementation does not renormalize the page rank vector after each iteration. Note that the old=FALSE method is not stable, is does not necessarily converge to a fixed point. It should be avoided for new code, it is only included for compatibility with old igraph versions.

Please note that the PageRank of a given vertex depends on the PageRank of all other vertices, so even if you want to calculate the PageRank for only some of the vertices, all of them must be calculated. Requesting the PageRank for only some of the vertices does not result in any performance increase at all.

Since the calculation is an iterative process, the algorithm is stopped after a given count of iterations or if the PageRank value differences between iterations are less than a predefined value.

Value

For page.rank a named list with entries:

vector A numeric vector with the PageRank scores.

value The eigenvalue corresponding to the eigenvector with the page rank scores. It should be always exactly one.
options Some information about the underlying ARPACK calculation. See arpack for
details. This entry is NULL if not the ARPACK implementation was used.

For page.rank.old a numeric vector of Page Rank scores.

permute.vertices

Permute the vertices of a graph

Description

Create a new graph, by permuting vertex ids.

Usage

permute.vertices(graph, permutation)

Arguments

graph The input graph, it can directed or undirected.

permutation A numeric vector giving the permutation to apply. The first element is the new
id of vertex 1, etc. Every number between one and vcount(graph) must appear
exactly once.
Pie charts as vertices

Details

This function creates a new graph from the input graph by permuting its vertices according to the specified mapping. Call this function with the output of `canonical.permutation` to create the canonical form of a graph.

`permute.vertices` keeps all graph, vertex and edge attributes of the graph.

Value

A new graph object.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

See Also

`canonical.permutation`

Examples

```r
# Random permutation of a random graph
g <- random.graph.game(20, 50, type="gnm")
g2 <- permute.vertices(g, sample(vcount(g)))
graph.isomorphic(g, g2)

# Permutation keeps all attributes
g$name <- "Random graph, Gnm, 20, 50"
V(g)$name <- letters[1:vcount(g)]
E(g)$weight <- sample(1:5, ecount(g), replace=TRUE)
g2 <- permute.vertices(g, sample(vcount(g)))
graph.isomorphic(g, g2)
g2$name
V(g2)$name
E(g2)$weight
all(sort(E(g2)$weight) == sort(E(g)$weight))
```

Pie charts as vertices

Using pie charts as vertices in graph plots

Description

More complex vertex images can be used to express additional information about vertices. E.g. pie charts can be used as vertices, to denote vertex classes, fuzzy classification of vertices, etc.
Details

The vertex shape 'pie' makes igraph draw a pie chart for every vertex. There are some extra graphical vertex parameters that specify how the pie charts will look like:

- **pie** Numeric vector, gives the sizes of the pie slices.
- **pie.color** A list of color vectors to use for the pies. If it is a list of a single vector, then this is used for all pies. If the color vector is shorter than the number of areas in a pie, then it is recycled.
- **pie.border** The color of the border line of the pie charts, in the same format as `pie.color`.
- **pie.angle** The slope of shading lines, given as an angle in degrees (counter-clockwise).
- **pie.density** The density of the shading lines, in lines per inch. Non-positive values inhibit the drawing of shading lines.
- **pie.lty** The line type of the border of the slices.

`igraph.plotting`, `plot.igraph`

Examples

```r
# Ring graph

# Create a ring graph with 10 vertices and random colors

g <- graph.ring(10)
values <- lapply(1:10, function(x) sample(1:10, 3))
if (interactive()) {
  plot(g, vertex.shape="pie", vertex.pie=values,
       vertex.pie.color=list(heat.colors(5)),
       vertex.size=seq(10,30,length=10), vertex.label=NA)
}
```

plot.igraph

**Plotting of graphs**

Description

`plot.igraph` is able to plot graphs to any R device. It is the non-interactive companion of the `tkplot` function.

Usage

```r
## S3 method for class 'igraph'
plot(x, axes=FALSE, add=FALSE,
     xlim=c(-1,1), ylim=c(-1,1),
     mark.groups=list(), mark.shape=1/2,
     mark.col=rainbow(length(mark.groups), alpha=0.3),
     mark.border=rainbow(length(mark.groups), alpha=1),
     mark.expand=15, ...)
```
Arguments

- **x**: The graph to plot.
- **axes**: Logical, whether to plot axes, defaults to FALSE.
- **add**: Logical scalar, whether to add the plot to the current device, or delete the device's current contents first.
- **xlim**: The limits for the horizontal axis, it is unlikely that you want to modify this.
- **ylim**: The limits for the vertical axis, it is unlikely that you want to modify this.
- **mark.groups**: A list of vertex id vectors. It is interpreted as a set of vertex groups. Each vertex group is highlighted, by plotting a colored smoothed polygon around and "under" it. See the arguments below to control the look of the polygons.
- **mark.shape**: A numeric scalar or vector. Controls the smoothness of the vertex group marking polygons. This is basically the 'shape' parameter of the `xspline` function, its possible values are between -1 and 1. If it is a vector, then a different value is used for the different vertex groups.
- **mark.col**: A scalar or vector giving the colors of marking the polygons, in any format accepted by `xspline`: e.g. numeric color ids, symbolic color names, or colors in RGB.
- **mark.border**: A scalar or vector giving the colors of the borders of the vertex group marking polygons. If it is NA, then no border is drawn.
- **mark.expand**: A numeric scalar or vector, the size of the border around the marked vertex groups. It is in the same units as the vertex sizes. If a vector is given, then different values are used for the different vertex groups.
- **...**: Additional plotting parameters. See `igraph.plotting` for the complete list.

Details

One convenient way to plot graphs is to plot with `tkplot` first, handtune the placement of the vertices, query the coordinates by the `tkplot.getcoords` function and use them with `plot` to plot the graph to any R device.

Value

Returns NULL, invisibly.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

See Also

- `layout` for different layouts, `igraph.plotting` for the detailed description of the plotting parameters and `tkplot` and `rglplot` for other graph plotting functions.

Examples

```r
  g <- graph.ring(10)
  # Not run: plot(g, layout=layout.kamada.kawai, vertex.color="green")
```
Description

This function can conveniently plot the results of multiple SIR model simulations.

Usage

```r
# S3 method for class 'sir'
plot(x, comp = c("NI", "NS", "NR"), median = TRUE,
     quantiles = c(0.1, 0.9), color = NULL, median_color = NULL,
     quantile_color = NULL, lwd.median = 2, lwd.quantile = 2,
     lty.quantile = 3, xlab = NULL, ylab = NULL, ...
```

Arguments

- `x`: The output of the SIR simulation, coming from the `sir` function.
- `comp`: Character scalar, which component to plot. Either ‘NI’ (infected, default), ‘NS’ (susceptible) or ‘NR’ (recovered).
- `median`: Logical scalar, whether to plot the (binned) median.
- `quantiles`: A vector of (binned) quantiles to plot.
- `color`: Color of the individual simulation curves.
- `median_color`: Color of the median curve.
- `quantile_color`: Color(s) of the quantile curves. (It is recycled if needed and non-needed entries are ignored if too long.)
- `lwd.median`: Line width of the median.
- `lwd.quantile`: Line width of the quantile curves.
- `lty.quantile`: Line type of the quantile curves.
- `xlab`: The x label.
- `ylab`: The y label. If NULL then it is automatically added based on the comp argument.
- `...`: Additional arguments are passed to `plot`, that is run before any of the curves are added, to create the figure.

Details

The number of susceptible/infected/recovered individuals is plotted over time, for multiple simulations.
power.law.fit

Description

power.law.fit fits a power-law distribution to a data set.

Usage

power.law.fit(x, xmin=NULL, start=2, force.continuous=FALSE, implementation=c("plfit", "R.mle"), ...)

Arguments

x
The data to fit, a numeric vector. For implementation ‘R.mle’ the data must be integer values. For the ‘plfit’ implementation non-integer values might be present and then a continuous power-law distribution is fitted.

xmin
Numeric scalar, or NULL. The lower bound for fitting the power-law. If NULL, the smallest value in x will be used for the ‘R.mle’ implementation, and its value will be automatically determined for the ‘plfit’ implementation. This argument makes it possible to fit only the tail of the distribution.

start
Numeric scalar. The initial value of the exponent for the minimizing function, for the ‘R.mle’ implementation. Usually it is safe to leave this untouched.
force.continuous
Logical scalar. Whether to force a continuous distribution for the 'plfit' implementation, even if the sample vector contains integer values only (by chance). If this argument is false, igraph will assume a continuous distribution if at least one sample is non-integer and assume a discrete distribution otherwise.

implementation
Character scalar. Which implementation to use. See details below.

... Additional arguments, passed to the maximum likelihood optimizing function, mle, if the 'R.mle' implementation is chosen. It is ignored by the 'plfit' implementation.

Details
This function fits a power-law distribution to a vector containing samples from a distribution (that is assumed to follow a power-law of course). In a power-law distribution, it is generally assumed that \( P(X = x) \) is proportional to \( x^{-\alpha} \), where \( x \) is a positive number and \( \alpha \) is greater than 1. In many real-world cases, the power-law behaviour kicks in only above a threshold value \( x_{\text{min}} \). The goal of this function is to determine \( \alpha \) if \( x_{\text{min}} \) is given, or to determine \( x_{\text{min}} \) and the corresponding value of \( \alpha \).

power.law.fit provides two maximum likelihood implementations. If the implementation argument is 'R.mle', then the BFGS optimization (see mle) algorithm is applied. The additional arguments are passed to the mle function, so it is possible to change the optimization method and/or its parameters. This implementation can not to fit the \( x_{\text{min}} \) argument, so use the 'plfit' implementation if you want to do that.

The 'plfit' implementation also uses the maximum likelihood principle to determine \( \alpha \) for a given \( x_{\text{min}} \): When \( x_{\text{min}} \) is not given in advance, the algorithm will attempt to find its optimal value for which the \( p \)-value of a Kolmogorov-Smirnov test between the fitted distribution and the original sample is the largest. The function uses the method of Clauset, Shalizi and Newman to calculate the parameters of the fitted distribution. See references below for the details.

Value
Depends on the implementation argument. If it is 'R.mle', then an object with class 'mle'. It can be used to calculate confidence intervals and log-likelihood. See mle-class for details.

If implementation is 'plfit', then the result is a named list with entries:

- continuous Logical scalar, whether the fitted power-law distribution was continuous or discrete.
- alpha Numeric scalar, the exponent of the fitted power-law distribution.
- xmin Numeric scalar, the minimum value from which the power-law distribution was fitted. In other words, only the values larger than xmin were used from the input vector.
- logLik Numeric scalar, the log-likelihood of the fitted parameters.
- KS.stat Numeric scalar, the test statistic of a Kolmogorov-Smirnov test that compares the fitted distribution with the input vector. Smaller scores denote better fit.
- KS.p Numeric scalar, the \( p \)-value of the Kolmogorov-Smirnov test. Small \( p \)-values (less than 0.05) indicate that the test rejected the hypothesis that the original data could have been drawn from the fitted power-law distribution.

Examples

# This should approximately yield the correct exponent 3
g <- barabasi.game(1000) # increase this number to have a better estimate
d <- degree(g, mode="in")
fit1 <- power.law.fit(d+1, 10)
fit2 <- power.law.fit(d+1, 10, implementation="R.mle")

fit1$alpha
coeff(fit2)
fit1$logLik
logLik(fit2)

Description

Generation of random graphs based on different vertex types.

Usage

preference.game(nodes, types, type.dist=rep(1, types), fixed.sizes=FALSE,
                pref.matrix=matrix(1, types, types), directed=FALSE, loops=FALSE)
asymmetric.preference.game(nodes, types,
                         type.dist.matrix=matrix(1,types,types),
                         pref.matrix = matrix(1, types, types), loops=FALSE)
Arguments

nodes The number of vertices in the graphs.
types The number of different vertex types.
type.dist The distribution of the vertex types, a numeric vector of length ‘types’ containing non-negative numbers. The vector will be normed to obtain probabilities.
fixed.sizes Fix the number of vertices with a given vertex type label. The type.dist argument gives the group sizes (i.e. number of vertices with the different labels) in this case.
type.dist.matrix The joint distribution of the in- and out-vertex types.
pref.matrix A square matrix giving the preferences of the vertex types. The matrix has ‘types’ rows and columns.
directed Logical constant, whether to create a directed graph.
loops Logical constant, whether self-loops are allowed in the graph.

details

Both models generate random graphs with given vertex types. For preference.game the probability that two vertices will be connected depends on their type and is given by the ‘pref.matrix’ argument. This matrix should be symmetric to make sense but this is not checked. The distribution of the different vertex types is given by the ‘type.dist’ vector.

For asymmetric.preference.game each vertex has an in-type and an out-type and a directed graph is created. The probability that a directed edge is realized from a vertex with a given out-type to a vertex with a given in-type is given in the ‘pref.matrix’ argument, which can be asymmetric. The joint distribution for the in- and out-types is given in the ‘type.dist.matrix’ argument.

Value

An igraph graph.

Author(s)

Tamas Nepusz <ntamas@gmail.com> and Gabor Csardi <csardi.gabor@gmail.com> for the R interface

establishment.game, callaway.traits.game

Examples

pf <- matrix( c(1, 0, 0, 1), nr=2)
g <- preference.game(20, 2, pref.matrix=pf)
## Not run: tkplot(g, layout=layout.fruchterman.reingold)

pf <- matrix( c(0, 1, 0, 0), nr=2)
g <- asymmetric.preference.game(20, 2, pref.matrix=pf)
## Not run: tkplot(g, layout=layout.circle)
Description

These functions attempt to print a graph to the terminal in a human readable form.

Usage

```r
## S3 method for class 'igraph'
print(x, full=getIgraphOpt("print.full"),
  graph.attributes=getIgraphOpt("print.graph.attributes"),
  vertex.attributes=getIgraphOpt("print.vertex.attributes"),
  edge.attributes=getIgraphOpt("print.edge.attributes"),
  names=TRUE, ...)
## S3 method for class 'igraph'
summary(object, ...)
## S3 method for class 'igraph'
str(object, ...)
```

Arguments

- `x` The graph to print.
- `full` Logical scalar, whether to print the graph structure itself as well.
- `graph.attributes` Logical constant, whether to print graph attributes.
- `vertex.attributes` Logical constant, whether to print vertex attributes.
- `edge.attributes` Logical constant, whether to print edge attributes.
- `names` Logical constant, whether to print symbolic vertex names (ie. the name vertex attribute) or vertex ids.
- `object` The graph of which the summary will be printed.
- `...` Additional arguments.

Details

- `summary.igraph` prints the number of vertices, edges and whether the graph is directed.
- `str.igraph` prints the same information, and also lists the edges, and optionally graph, vertex and/or edge attributes.
- `print.igraph` behaves either as `summary.igraph` or `str.igraph` depending on the `full` argument. See also the 'print.full' igraph option and `getIgraphOpt`.

The graph summary printed by `summary.igraph` (and `print.igraph` and `str.igraph`) consists one or more lines. The first line contains the basic properties of the graph, and the rest contains its attributes. Here is an example, a small star graph with weighed directed edges and named vertices:
The read.graph function is able to read graphs in various representations from a file, or from an http connection. Currently some simple formats are supported.

Usage

```
read.graph(file, format = c("edgelist", "pajek", "ncol", "lgl",
                         "graphml", "dimacs", "graphdb", "gml", "dl"), ...)```

**Value**

All these functions return the graph invisibly.
Arguments

file The connection to read from. This can be a local file, or a http or ftp connection. It can also be a character string with the file name or URI.

format Character constant giving the file format. Right now edgelist, pajek, graphml, gml, ncol, lgl, dimacs and graphdb are supported, the default is edgelist. As of igraph 0.4 this argument is case insensitive.

... Additional arguments, see below.

Details

The read.graph function may have additional arguments depending on the file format (the format argument). See the details separately for each file format, below.

Value

A graph object.

Edge list format

This format is a simple text file with numeric vertex ids defining the edges. There is no need to have newline characters between the edges, a simple space will also do.

Additional arguments:

n The number of vertices in the graph. If it is smaller than or equal to the largest integer in the file, then it is ignored; so it is safe to set it to zero (the default).

directed Logical scalar, whether to create a directed graph. The default value is TRUE.

Pajek format

Pajek it a popular network analysis program for Windows. (See the Pajek homepage at http://vlado.fmf.uni-lj.si/pub/networks/pajek/) It has a quite flexible but not very well documented file format, see the Pajek manual on the Pajek homepage for some information about the file format.

igraph implements only a subset of the Pajek format:

• Only .net files are supported. Pajek project files (which can contain many graph and also other type of data) are not. Project files might be supported in a forthcoming igraph release if they turned out to be needed.
• Time events networks are not supported.
• Hypergraphs (graphs with non-binary edges) are not supported as igraph cannot handle them.
• Graphs containing both directed and undirected edges are not supported as igraph cannot represent them.
• Graph with multiple edge sets are not supported.

From version 0.6.1 igraph supports reading bipartite (two-mode) graphs from Pajek files and adds the type vertex attribute. A warning is given if invalid edges (edges connecting vertices of the same type) are present in the file.
Vertex and edge attributes defined in the Pajek file will be also read and assigned to the graph object to be created. These are mainly parameters for graph visualization, but not exclusively, eg. the file might contain edge weights as well.

The following vertex attributes might be added:

<table>
<thead>
<tr>
<th>igraph name</th>
<th>description, Pajek attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>Vertex id</td>
</tr>
<tr>
<td>x, y, z</td>
<td>The ‘x’, ‘y’ and ‘z’ coordinate of the vertex</td>
</tr>
<tr>
<td>vertexsize</td>
<td>The size of the vertex when plotted (size in Pajek).</td>
</tr>
<tr>
<td>shape</td>
<td>The shape of the vertex when plotted.</td>
</tr>
<tr>
<td>color</td>
<td>Vertex color (lc in Pajek) if given with symbolic name</td>
</tr>
<tr>
<td>framecolor</td>
<td>Border color (bc in Pajek) if given with symbolic name</td>
</tr>
<tr>
<td>labelcolor</td>
<td>Label color (lc in Pajek) if given with symbolic name</td>
</tr>
<tr>
<td>xfact, yfact</td>
<td>The x_fact and y_fact Pajek attributes.</td>
</tr>
<tr>
<td>labeldist</td>
<td>The distance of the label from the vertex. (1r in Pajek.)</td>
</tr>
<tr>
<td>labeldegree,</td>
<td>The la and lphi Pajek attributes</td>
</tr>
<tr>
<td>labeldegree2</td>
<td></td>
</tr>
<tr>
<td>linewidth</td>
<td>The width of the border (bw in Pajek).</td>
</tr>
<tr>
<td>fontsize</td>
<td>Size of the label font (fos in Pajek).</td>
</tr>
<tr>
<td>rotation</td>
<td>The rotation of the vertex (phi in Pajek).</td>
</tr>
<tr>
<td>radius</td>
<td>Radius, for some vertex shapes (r in Pajek).</td>
</tr>
<tr>
<td>diamondratio</td>
<td>For the diamond shape (q in Pajek).</td>
</tr>
<tr>
<td>type</td>
<td>vertex types in bipartite (two-mode) graphs.</td>
</tr>
</tbody>
</table>

These igraph attributes are only created if there is at least one vertex in the Pajek file which has the corresponding associated information. Eg. if there are vertex coordinates for at least one vertex then the ‘x’, ‘y’ and possibly also ‘z’ vertex attributes will be created. For those vertices for which the attribute is not defined, NaN is assigned.

The following edge attributes might be added:

<table>
<thead>
<tr>
<th>igraph name</th>
<th>description, Pajek attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>weight</td>
<td>Edge weights.</td>
</tr>
<tr>
<td>label</td>
<td>1 in Pajek.</td>
</tr>
<tr>
<td>color</td>
<td>Edge color, if the color is given with a symbolic name, c in Pajek.</td>
</tr>
<tr>
<td>color-red,</td>
<td></td>
</tr>
<tr>
<td>color-green</td>
<td></td>
</tr>
<tr>
<td>color-blue</td>
<td>Edge color if it was given in RGB notation, c in Pajek.</td>
</tr>
<tr>
<td>edgewidth</td>
<td>w in Pajek.</td>
</tr>
<tr>
<td>arrowsize</td>
<td>s in Pajek.</td>
</tr>
<tr>
<td>hook1, hook2</td>
<td>h1 and h2 in Pajek.</td>
</tr>
<tr>
<td>angle1, angle2</td>
<td>a1 and a2 in Pajek, Bezier curve parameters.</td>
</tr>
<tr>
<td>velocity1,</td>
<td></td>
</tr>
<tr>
<td>velocity2</td>
<td>k1 and k2 in Pajek, Bezier curve parameter.</td>
</tr>
<tr>
<td>arrowpos</td>
<td>ap in Pajek.</td>
</tr>
<tr>
<td>labelpos</td>
<td>lp in Pajek.</td>
</tr>
<tr>
<td>labelangle,</td>
<td></td>
</tr>
<tr>
<td>labelangle2</td>
<td>1r and 1phi in Pajek.</td>
</tr>
</tbody>
</table>
There are no additional arguments for this format.

GraphML file format

GraphML is an XML-based file format (an XML application in the XML terminology) to describe graphs. It is a modern format, and can store graphs with an extensible set of vertex and edge attributes, and generalized graphs which igraph cannot handle. Thus igraph supports only a subset of the GraphML language:

- Hypergraphs are not supported.
- Nested graphs are not supported.
- Mixed graphs, ie. graphs with both directed and undirected edges are not supported. read.graph() sets the graph directed if this is the default in the GraphML file, even if all the edges are in fact undirected.

See the GraphML homepage at http://graphml.graphdrawing.org for more information about the GraphML format.

Additional arguments:

index If the GraphML file contains more than one graphs, this argument can be used to select the graph to read. By default the first graph is read (index 0).

GML file format

GML is a simple textual format, see http://www.fim.uni-passau.de/en/fim/faculty/chairs/theoretische-informatik/projects.html for details.

Although all syntactically correct GML can be parsed, we implement only a subset of this format, some attributes might be ignored. Here is a list of all the differences:

- Only node and edge attributes are used, and only if they have a simple type: integer, real or string. So if an attribute is an array or a record, then it is ignored. This is also true if only some values of the attribute are complex.
- Top level attributes except for Version and the first graph attribute are completely ignored.
- Graph attributes except for node and edge are completely ignored.
- There is no maximum line length.
- There is no maximum keyword length.
- Character entities in strings are not interpreted.
- We allow inf (infinity) and nan (not a number) as a real number. This is case insensitive, so nan, NaN and NAN are equal.

Please contact us if you cannot live with these limitations of the GML parser.

There are not additional argument for this format.
DL file format

The DL format is a simple textual file format used by the UCINET software. See http://www.analytictech.com/networks/dataentry.htm for examples. All formats mentioned here is supported by igraph.

Note the specification does not mention whether the format is case sensitive or not. For igraph DL files are case sensitive, i.e. ‘Larry’ and ‘larry’ are not the same.

Additional arguments:

- directed Logical scalar, whether to create a directed graph. The default is to make the graph directed.

NCOL format

This format is used by the Large Graph Layout program (http://bioinformatics.icmb.utexas.edu/lgl), and it is simply a symbolic weighted edge list. It is a simple text file with one edge per line. An edge is defined by two symbolic vertex names separated by whitespace. (The symbolic vertex names themselves cannot contain whitespace.) They might followed by an optional number, this will be the weight of the edge; the number can be negative and can be in scientific notation. If there is no weight specified to an edge it is assumed to be zero.

The resulting graph is always undirected. LGL cannot deal with files which contain multiple or loop edges, this is however not checked here, as igraph is happy with these.

Additional arguments:

- names Logical constant, whether to add the symbolic names as vertex attributes to the graph. If TRUE the name of the vertex attribute will be ‘name’.
- weights Character scalar, specifies whether edge weights should be added to the graph. Possible values are and their meaning are: ‘no’, edge weights will not be added; ‘yes’, edge weights will be added, if they are not present in the file, then all edges get zero weight; ‘auto’, edge weights will added if they are present in the file, otherwise not. The default is ‘auto’.

- directed Logical constant, whether to create a directed graph. The default is undirected.

LGL file format

The lgl format is used by the Large Graph Layout visualization software (http://bioinformatics.icmb.utexas.edu/lgl), it can describe undirected optionally weighted graphs. From the LGL manual: “The second format is the LGL file format (.lgl file suffix). This is yet another graph file format that tries to be as stingy as possible with space, yet keeping the edge file in a human readable (not binary) format. The format itself is like the following:

# vertex1name
vertex2name [optionalWeight]
vertex3name [optionalWeight]

Here, the first vertex of an edge is preceded with a pound sign ‘#’. Then each vertex that shares an edge with that vertex is listed one per line on subsequent lines.”
LGL cannot handle loop and multiple edges or directed graphs, but in igraph it is not an error to have multiple and loop edges.

Additional arguments:

- **names** Logical constant, whether to add the symbolic names as vertex attributes to the graph. If TRUE the name of the vertex attribute will be ‘name’.
- **weights** Character scalar, specifies whether edge weights should be added to the graph. Possible values are and their meaning are: ‘no’, edge weights will not be added; ‘yes’, edge weights will be added, if they are not present in the file, then all edges get zero weight; ‘auto’, edge weights will be added if they are present in the file, otherwise not. The default is ‘auto’.

**DIMACS file format**

The DIMACS file format, more specifically the version for network flow problems, see the files at [ftp://dimacs.rutgers.edu/pub/netflow/general-info/](ftp://dimacs.rutgers.edu/pub/netflow/general-info/)

This is a line-oriented text file (ASCII) format. The first character of each line defines the type of the line. If the first character is `c` the line is a comment line and it is ignored. There is one problem line (p) in the file, it must appear before any node and arc descriptor lines. The problem line has three fields separated by spaces: the problem type (`min`, `max` or `asn`), the number of vertices and number of edges in the graph. Exactly two node identification lines are expected (`n`), one for the source, one for the target vertex. These have two fields: the id of the vertex and the type of the vertex, either `s` (=source) or `t` (=target). Arc lines start with `a` and have three fields: the source vertex, the target vertex and the edge capacity.

Vertex ids are numbered from 1.

The source vertex is assigned to the source, the target vertex to the target graph attribute. The edge capacities are assigned to the capacity edge attribute.

Additional arguments:

- **directed** Logical scalar, whether to create a directed graph. By default a directed graph is created.

**GraphDB format**

This is a binary format, used in the graph database for isomorphism testing. From the (now defunct) graph database homepage:

> The graphs are stored in a compact binary format, one graph per file. The file is composed of 16 bit words, which are represented using the so-called little-endian convention, i.e. the least significant byte of the word is stored first.

> Then, for each node, the file contains the list of edges coming out of the node itself. The list is represented by a word encoding its length, followed by a word for each edge, representing the destination node of the edge. Node numeration is 0-based, so the first node of the graph has index 0.

See also `graph.graphdb`.

Only unlabelled graphs are implemented.

Additional attributes:
**directed** Logical scalar. Whether to create a directed graph.

**Author(s)**
Gabor Csardi <csardi.gabor@gmail.com>

**See Also**
write.graph

---

**reciprocity**

Reciprocity of graphs

**Description**
Calculates the reciprocity of a directed graph.

**Usage**

```r
reciprocity(graph, ignore.loops = TRUE, mode = c("default", "ratio"))
```

**Arguments**
- `graph` The graph object.
- `ignore.loops` Logical constant, whether to ignore loop edges.
- `mode` See below.

**Details**
The measure of reciprocity defines the proportion of mutual connections, in a directed graph. It is most commonly defined as the probability that the opposite counterpart of a directed edge is also included in the graph. Or in adjacency matrix notation: \( \sum_{ij} (A \cdot A')_{ij} \), where \( A \cdot A' \) is the element-wise product of matrix \( A \) and its transpose. This measure is calculated if the mode argument is default.

Prior to igraph version 0.6, another measure was implemented, defined as the probability of mutual connection between a vertex pair, if we know that there is a (possibly non-mutual) connection between them. In other words, (unordered) vertex pairs are classified into three groups: (1) not-connected, (2) non-reciprocally connected, (3) reciprocally connected. The result is the size of group (3), divided by the sum of group sizes (2)+(3). This measure is calculated if mode is ratio.

**Value**
A numeric scalar between zero and one.

**Author(s)**
Tamas Nepusz <ntamas@gmail.com> and Gabor Csardi <csardi.gabor@gmail.com>
Examples

```r
g <- random.graph.game(20, 5/20, directed=TRUE)
reciprocity(g)
```

Description

These functions assume a simple evolving network model and measure the functional form of a so-called *attractiveness function* governing the evolution of the network.

Usage

```r
evolver.d (nodes, kernel, outseq = NULL, outdist = NULL, m = 1, directed = TRUE)
evolver.d (graph, niter=5, sd=FALSE, norm=FALSE, cites=FALSE, expected=FALSE, error=TRUE, debug=numeric())
evolver.ad (graph, niter=5, agebins=max(vcount(graph)/7100, 10), sd=FALSE, norm=FALSE, cites=FALSE, expected=FALSE, error=TRUE, debug=matrix(ncol=2, nrow=0))
evolver.ade (graph, cats, niter=5, agebins=max(vcount(graph)/7100, 10), sd=FALSE, norm=FALSE, cites=FALSE, expected=FALSE, error=TRUE, debug=matrix(ncol=2, nrow=0))

Arguments

- **nodes**: The number of vertices in the generated network.
- **kernel**: The kernel function, a vector, matrix or array, depending on the number of model parameters.
- **outseq**: The out-degree sequence, or NULL if no out-degree sequence is used.
- **outdist**: The out-degree distribution, or NULL if all vertices have the same out-degree. This argument is ignored if the outseq argument is not NULL.
- **m**: Numeric scalar, the out-degree of the vertex. It is ignored if at least one of outseq and outdist is not NULL.
- **directed**: Logical scalar, whether to create a directed graph.
- **graph**: The input graph.
- **niter**: The number of iterations to perform.
- **sd**: Logical scalar, whether to return the standard deviation of the estimates.
- **norm**: Logical scalar, whether to return the normalizing factors.
- **cites**: Logical scalar, whether to return the number of citations to the different vertex types.
- **expected**: Logical scalar, whether to return the expected number of citations for the different vertex types.
error Logical scalar, whether to return the error of the fit.

dbg Currently not used.
agebins The number of bins for vertex age.
cats The number of categories to use.
width The width of the time window to use, measured in number of vertices.
vtime Numeric vector, the time steps when the vertices were added to the network.
etime Numeric vector, the time steps when the edges were added to the network.
events A list of numeric vectors, each vector represents an event, with the participation of the listed vertices.
delta Real scalar, the error margin that is allowed for the convergence.
filter Logical vector, length is the number of vertices. Only vertices corresponding to TRUE entries are used in the fitting.
alpha Starting value for the ‘alpha’ parameter.
a Starting value for the ‘a’ parameter.
palpha Starting value for the ‘paralpha’ (Pareto alpha) parameter.
pbeta Starting value for the ‘parbeta’ (Pareto beta) parameter.
parscale Starting value for the ‘parscale’ (Pareto scale) parameter.
abstol Real scalar, absolute tolerance for the ML fitting.
reoltol Real scalar, relative tolerance for the ML fitting.
maxit Numeric scalar, the maximum number of iterations.
beta Real scalar, starting value for the ‘beta’ parameter.
ceffs Numeric vector, starting values for the coefficients.
par Pareto parameters for the different vertex types, in a matrix.
ntk Logical scalar, whether to return the Ntk values.
gcats Numeric vector, the vertex types.
st Logical scalar, whether to return the S(t) values.

Details

The functions should be considered as experimental, so no detailed documentation yet. Sorry.

Value

A named list.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>
Description
Randomly rewires a graph while preserving the degree distribution.

Usage
rewire(graph, mode = c("simple", "loops"), niter = 100)

Arguments
graph  The graph to be rewired.
mode   The rewiring algorithm to be used. It can be one of the following: simple: simple rewiring algorithm which chooses two arbitrary edges in each step (namely (a,b) and (c,d)) and substitutes them with (a,d) and (c,b) if they don’t yet exist, avoiding the creation or destruction of loop edges or loops: similar to simple but allows the creation and destruction of loop edges.
niter  Number of rewiring trials to perform.

Details
This function generates a new graph based on the original one by randomly rewiring edges while preserving the original graph’s degree distribution.

Value
A new graph object.

Author(s)
Tamas Nepusz <ntamas@gmail.com> and Gabor Csardi <csardi.gabor@gmail.com>

See Also
degree.sequence.game

Examples
```r
g <- graph.ring(20)
g2 <- rewire(g, niter=3)
```
rewire.edges

Rewires the endpoints of the edges of a graph randomly

Description

This function rewires the endpoints of the edges with a constant probability uniformly randomly to a new vertex in a graph.

Usage

rewire.edges(graph, prob, loops=FALSE, multiple=FALSE)

Arguments

graph The input graph
prob The rewiring probability, a real number between zero and one.
loops Logical scalar, whether loop edges are allowed in the rewired graph.
multiple Logical scalar, whether multiple edges are allowed in the generated graph.

Details

Note that this function might create graphs with multiple and/or loop edges.

Value

A new graph object.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

Examples

# Some random shortcuts shorten the distances on a lattice
g <- graph.lattice( length=100, dim=1, nei=5 )
average.path.length(g)
g <- rewire.edges( g, prob=0.05 )
average.path.length(g)
rglplot

3D plotting of graphs with OpenGL

Description

Using the rgl package, rglplot plots a graph in 3D. The plot can be zoomed, rotated, shifted, etc. but the coordinates of the vertices is fixed.

Usage

rglplot(x, ...)

Arguments

x  

The graph to plot.

...  

Additional arguments, see igraph.plotting for the details

Details

Note that rglplot is considered to be highly experimental. It is not very useful either. See igraph.plotting for the possible arguments.

Value

NULL, invisibly.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

igraph.plotting, plot.igraph for the 2D version, tkplot for interactive graph drawing in 2D.

Examples

```r
## Not run:
g <- graph.lattice( c(5,5,5) )
coords <- layout.fruchterman.reingold(g, dim=3)
rglplot(g, layout=coords)

## End(Not run)
```
### running.mean

**Running mean of a time series**

**Description**

running.mean calculates the running mean in a vector with the given bin width.

**Usage**

```
running.mean(v, binwidth)
```

**Arguments**

- **v**: The numeric vector.
- **binwidth**: Numeric constant, the size of the bin, should be meaningful, i.e. smaller than the length of `v`.

**Details**

The running mean of `v` is a `w` vector of length `length(v)-binwidth+1`. The first element of `w` is the average of the first `binwidth` elements of `v`, the second element of `w` is the average of elements `2:(binwidth+1)`, etc.

**Value**

A numeric vector of length `length(v)-binwidth+1`

**Author(s)**

Gabor Csardi <csardi.gabor@gmail.com>

**Examples**

```
running.mean(1:100, 10)
```

---

### sbm.game

**Sample stochastic block model**

**Description**

Sampling from the stochastic block model of networks

**Usage**

```
sbm.game (n, pref.matrix, block.sizes, directed = FALSE, loops = FALSE)
```
sbm.game

Arguments

n Number of vertices in the graph.
pref.matrix The matrix giving the Bernoulli rates. This is a $K \times K$ matrix, where $K$ is the number of groups. The probability of creating an edge between vertices from groups $i$ and $j$ is given by element $(i,j)$. For undirected graphs, this matrix must be symmetric.
block.sizes Numeric vector giving the number of vertices in each group. The sum of the vector must match the number of vertices.
directed Logical scalar, whether to generate a directed graph.
loops Logical scalar, whether self-loops are allowed in the graph.

Details

This function samples graphs from a stochastic block model by (doing the equivalent of) Bernoulli trials for each potential edge with the probabilities given by the Bernoulli rate matrix, `pref.matrix`.

Value

An igraph graph.

g
```
All-in-one Function for the SCG of Matrices and Graphs

Description

This function handles all the steps involved in the Spectral Coarse Graining (SCG) of some matrices and graphs as described in the reference below.

Usage

scg(X, ev, nt, groups = NULL, mtype = c("symmetric", "laplacian", "stochastic"), algo = c("optimum", "interv_km", "interv", "exact_scg"), norm = c("row", "col"), direction = c("default", "left", "right"), evec = NULL, p = NULL, use.arpack = FALSE, maxiter = 300, sparse = getIgraphOpt("sparsematrices"), output = c("default", "matrix", "graph"), semproj = FALSE, epairs = FALSE, stat.prob = FALSE)

Arguments

X
The input graph or square matrix. Can be of class igraph, matrix or Matrix.

ev
A vector of positive integers giving the indexes of the eigenpairs to be preserved. For real eigenpairs, 1 designates the eigenvalue with largest algebraic value, 2 the one with second largest algebraic value, etc. In the complex case, it is the magnitude that matters.

nt
A vector of positive integers of length one or equal to length(ev). When algo = "optimum", nt contains the number of groups used to partition each eigenvector separately. When algo is equal to "interv\_km" or "interv", nt contains the number of intervals used to partition each eigenvector. The same partition size or number of intervals is used for each eigenvector if nt is a single integer. When algo = "exact\_scg" this parameter is ignored.

groups
A vector of nrow(X) or vcount(X) integers labeling each group vertex in the partition. If this parameter is supplied most part of the function is bypassed.

mtype
Character scalar. The type of semi-projector to be used for the SCG. For now "symmetric", "laplacian" and "stochastic" are available.

algo
Character scalar. The algorithm used to solve the SCG problem. Possible values are "optimum", "interv\_km", "interv" and "exact\_scg".

norm
Character scalar. Either "row" or "col". If set to "row" the rows of the Laplacian matrix sum up to zero and the rows of the stochastic matrix sum up to one; otherwise it is the columns.

direction
Character scalar. When set to "right", "left", the parameters ev and evec refer to right, resp. left eigenvectors. When passed "default" it is the SCG described in the reference below that is applied (common usage). This argument is currently not implemented, and right eigenvectors are always used.
scg

A numeric matrix of (eigen)vectors to be preserved by the coarse graining (the vectors are to be stored column-wise in `evec`). If supplied, the eigenvectors should correspond to the indexes in `ev` as no cross-check will be done.

A probability vector of length `nrow(X)` (or `vcount(X)`). `p` is the stationary probability distribution of a Markov chain when `mtype = "stochastic"`. This parameter is ignored in all other cases.

Logical scalar. When set to `TRUE` uses the function `arpack` to compute eigenpairs. This parameter should be set to `TRUE` if one deals with large (over a few thousands) AND sparse graphs or matrices. This argument is not implemented currently and LAPACK is used for solving the eigenproblems.

A positive integer giving the maximum number of iterations for the k-means algorithm when `algo = "interv_km"`. This parameter is ignored in all other cases.

Logical scalar. Whether to return sparse matrices in the result, if matrices are requested.

Character scalar. Set this parameter to "default" to retrieve a coarse-grained object of the same class as `x`.

Logical scalar. Set this parameter to `TRUE` to retrieve the semi-projectors of the SCG.

Logical scalar. Set this to `TRUE` to collect the eigenpairs computed by `scg`.

Logical scalar. This is to collect the stationary probability `p` when dealing with stochastic matrices.

Please see `SCG` for an introduction.

In the following `V` is the matrix of eigenvectors for which the SCG is solved. `V` is calculated from `X`, if it is not given in the `evec` argument.

The algorithm “optimum” solves exactly the SCG problem for each eigenvector in `V`. The running time of this algorithm is $O(\max nt \cdot m^2)$ for the symmetric and laplacian matrix problems (i.e. when `mtype` is “symmetric” or “laplacian”. It is $O(m^3)$ for the stochastic problem. Here `m` is the number of rows in `V`. In all three cases, the memory usage is $O(m^2)$.

The algorithms “interv” and “interv_km” solve approximately the SCG problem by performing a (for now) constant binning of the components of the eigenvectors, that is `nt[1]` constant-size bins are used to partition `V[,1]`. When `algo = "interv_km"`, the (Lloyd) k-means algorithm is run on each partition obtained by “interv” to improve accuracy.

Once a minimizing partition (either exact or approximate) has been found for each eigenvector, the final grouping is worked out as follows: two vertices are grouped together in the final partition if they are grouped together in each minimizing partition. In general the size of the final partition is not known in advance when `ncol(V)>1`.

Finally, the algorithm “exact_scg” groups the vertices with equal components in each eigenvector. The last three algorithms essentially have linear running time and memory load.

## End(Not run)
Description

Some useful functions to perform general actions in Spectral Coarse Graining (SCG).

Usage

```
scgnormeps(V, groups, mtype = c("symmetric", "laplacian", "stochastic"), p = NULL, norm = c("row", "col"))
```

Arguments

- **V**: A numeric matrix of (eigen)vectors assumed normalized. The vectors are to be stored column-wise in V.
- **groups**: A vector of nrow(V) integers labeling each group vertex in the partition.
- **mtype**: The type of semi-projector used for the SCG. For now “symmetric”, “laplacian” and “stochastic” are available.
- **p**: A probability vector of length nrow(V). p is the stationary probability distribution of a Markov chain when mtype = “stochastic”. This parameter is ignored otherwise.
- **norm**: Either “row” or “col”. If set to “row” the rows of the Laplacian matrix sum to zero and the rows of the stochastic matrix sum to one; otherwise it is the columns.

Details

`scgnormeps` computes $\|v_i - Pv_i\|$, where $v_i$ is the $i$th eigenvector in V and $P$ is the projector corresponding to the mtype argument.

Value

`normeps` returns with a numeric vector whose $i$th component is $\|v_i - Pv_i\|$ (see Details).

km <- kmeans(v, 5)
sum(km$withinss)
scgNormEps(cbind(v, km$cluster)^2
```

---

**scgGrouping**

**SCG Problem Solver**

**Description**

This function solves the Spectral Coarse Graining (SCG) problem; either exactly, or approximately but faster.

**Usage**

```r
scgGrouping(V, nt, mtype = c("symmetric", "laplacian", "stochastic"), algo = c("optimum", "interv_km", "interv","exact_scg"), p = NULL, maxiter = 100)
```

**Arguments**

- **V**
  A numeric matrix of (eigen)vectors to be preserved by the coarse graining (the vectors are to be stored column-wise in V).

- **nt**
  A vector of positive integers of length one or equal to length(ev). When algo = “optimum”, nt contains the number of groups used to partition each eigenvector separately. When algo is equal to “interv\_km” or “interv”, nt contains the number of intervals used to partition each eigenvector. The same partition size or number of intervals is used for each eigenvector if nt is a single integer. When algo = “exact\_scg” this parameter is ignored.

- **mtype**
  The type of semi-projectors used in the SCG. For now “symmetric”, “laplacian” and “stochastic” are available.

- **algo**
  The algorithm used to solve the SCG problem. Possible values are “optimum”, “interv\_km”, “interv” and “exact\_scg”.

- **p**
  A probability vector of length equal to nrow(V). p is the stationary probability distribution of a Markov chain when mtype = “stochastic”. This parameter is ignored in all other cases.

- **maxiter**
  A positive integer giving the maximum number of iterations of the k-means algorithm when algo = “interv\_km”. This parameter is ignored in all other cases.
Details

The algorithm “optimum” solves exactly the SCG problem for each eigenvector in $V$. The running time of this algorithm is $O(\max nt \cdot m^2)$ for the symmetric and laplacian matrix problems (i.e. when mtype is “symmetric” or “laplacian”. It is $O(m^3)$ for the stochastic problem. Here $m$ is the number of rows in $V$. In all three cases, the memory usage is $O(m^2)$.

The algorithms “interv” and “interv\_km” solve approximately the SCG problem by performing a (for now) constant binning of the components of the eigenvectors, that is nt[i] constant-size bins are used to partition $V[.,i]$. When algo = “interv\_km”, the (Lloyd) k-means algorithm is run on each partition obtained by “interv” to improve accuracy.

Once a minimizing partition (either exact or approximate) has been found for each eigenvector, the final grouping is worked out as follows: two vertices are grouped together in the final partition if they are grouped together in each minimizing partition. In general the size of the final partition is not known in advance when ncol($V$)>1.

Finally, the algorithm “exact\_scg” groups the vertices with equal components in each eigenvector. The last three algorithms essentially have linear running time and memory load.

Value

A vector of nrow($V$) integers giving the group label of each object (vertex) in the partition.

SCG for a detailed introduction. scg, scgnormeps

Examples

```r
# We are not running these examples any more, because they
# take a long time to run and this is against the CRAN repository
# policy. Copy and paste them by hand to your R prompt if
# you want to run them.

# Not run:
# eigenvectors of a random symmetric matrix
M <- matrix(rexp(10^6), 10^3, 10^3)
M <- (M + t(M))/2
V <- eigen(M, symmetric=TRUE)$vectors[,c(1,2)]
# displays size of the groups in the final partition
```
A function to compute the $L$ and $R$ semi-projectors for a given partition of the vertices.

Usage

scgSemiProjectors(groups, mtype = c("symmetric", "laplacian", "stochastic"), p = NULL, norm = c("row", "col"), sparse = getIgraphOpt("sparsematrices"))

Arguments

groups A vector of nrow(X) or vcount(X) integers giving the group label of every vertex in the partition.

mtype The type of semi-projectors. For now "symmetric", "laplacian" and "stochastic" are available.
p

A probability vector of length \text{length}(\text{gr}). \( p \) is the stationary probability distribution of a Markov chain when \text{mtype} = “stochastic”. This parameter is ignored in all other cases.

\text{norm}

Either “row” or “col”. If set to “row” the rows of the Laplacian matrix sum up to zero and the rows of the stochastic sum up to one; otherwise it is the columns.

\text{sparse}

Logical scalar, whether to return sparse matrices.

Details

The three types of semi-projectors are defined as follows. Let \( \gamma(j) \) label the group of vertex \( j \) in a partition of all the vertices.

The symmetric semi-projectors are defined as

\[
L_{\alpha j} = R_{\alpha j} = \frac{1}{|\alpha|} \delta_{\alpha \gamma(j)},
\]

the (row) Laplacian semi-projectors as

\[
L_{\alpha j} = \frac{1}{|\alpha|} \delta_{\alpha \gamma(j)} \quad \text{and} \quad R_{\alpha j} = \delta_{\alpha \gamma(j)},
\]

and the (row) stochastic semi-projectors as

\[
L_{\alpha j} = \frac{p_1(j)}{\sum_{k \in \gamma(j)} p_1(k)} \quad \text{and} \quad R_{\alpha j} = \delta_{\alpha \gamma(j)} \delta_{\alpha \gamma(j)},
\]

where \( p_1 \) is the (left) eigenvector associated with the one-eigenvalue of the stochastic matrix. \( L \) and \( R \) are defined in a symmetric way when \text{norm} = \text{col}. All these semi-projectors verify various properties described in the reference.

Value

L The semi-projector \( L \).

R The semi-projector \( R \).

**shortest.paths**

*Shortest (directed or undirected) paths between vertices*

**Description**

`shortest.paths` calculates the length of all the shortest paths from or to the vertices in the network.

`get.shortest.paths` calculates one shortest path (the path itself, and not just its length) from or to the given vertex.

**Usage**

```r
shortest.paths(graph, v=V(graph), to=V(graph),
               mode = c("all", "out", "in"),
               weights = NULL, algorithm = c("automatic", "unweighted",
               "dijkstra", "bellman-ford", 
               "johnson"))
get.shortest.paths(graph, from, to=V(graph), mode = c("out", "all", "in"),
                   weights = NULL, output=c("vpath", "epath", "both"),
                   predecessors = FALSE, inbound.edges = FALSE)
get.all.shortest.paths(graph, from, to = V(graph), mode = c("out", "all", "in"),
                        weights=NULL)
average.path.length(graph, directed=TRUE, unconnected=TRUE)
path.length.hist (graph, directed = TRUE)
```

**Examples**

```r
library(Matrix)
# compute the semi-projectors and projector for the partition
# provided by a community detection method
g <- barabasi.game(20, m=1.5)
eb <- edge.betweenness.community(g)
memb <- membership(eb)
lr <- scgSemiprojectors(memb)
#In the symmetric case L = R
tcrossprod(lr$R) # same as lr$R %*% t(lr$R)
P <- crossprod(lr$R) # same as t(lr$R) %*% lr$R
#P is an orthogonal projector
isSymmetric(P)
sum( (P %*% P-P)^2 )

## use L and R to coarse-grain the graph Laplacian
lr <- scgSemiprojectors(memb, mtype="laplacian")
L <- graph.laplacian(g)
Lt <- lr$L %*% L %*% t(lr$R)
## or better lr$L %*% tcrossprod(L,lr$R)
rowSums(Lt)
```
shortest.paths

Arguments

**graph**
The graph to work on.

**v**
Numeric vector, the vertices from which the shortest paths will be calculated.

**to**
Numeric vector, the vertices to which the shortest paths will be calculated. By default it includes all vertices. Note that for shortest.paths every vertex must be included here at most once. (This is not required for get.shortest.paths.

**mode**
Character constant, gives whether the shortest paths to or from the given vertices should be calculated for directed graphs. If **out** then the shortest paths from the vertex, if **in** then to it will be considered. If all, the default, then the corresponding undirected graph will be used, i.e. not directed paths are searched. This argument is ignored for undirected graphs.

**weights**
Possibly a numeric vector giving edge weights. If this is NULL and the graph has a weight edge attribute, then the attribute is used. If this is NA then no weights are used (even if the graph has a weight attribute).

**algorithm**
Which algorithm to use for the calculation. By default igraph tries to select the fastest suitable algorithm. If there are no weights, then an unweighted breadth-first search is used, otherwise if all weights are positive, then Dijkstra’s algorithm is used. If there are negative weights and we do the calculation for more than 100 sources, then Johnson’s algorithm is used. Otherwise the Bellman-Ford algorithm is used. You can override igraph’s choice by explicitly giving this parameter. Note that the igraph C core might still override your choice in obvious cases, i.e. if there are no edge weights, then the unweighted algorithm will be used, regardless of this argument.

**from**
Numeric constant, the vertex from or to the shortest paths will be calculated. Note that right now this is not a vector of vertex ids, but only a single vertex.

**output**
Character scalar, defines how to report the shortest paths. “vpath” means that the vertices along the paths are reported, this form was used prior to igraph version 0.6. “epath” means that the edges along the paths are reported. “both” means that both forms are returned, in a named list with components “vpath” and “epath”.

**predecessors**
Logical scalar, whether to return the predecessor vertex for each vertex. The predecessor of vertex \( i \) in the tree is the vertex from which vertex \( i \) was reached. The predecessor of the start vertex (in the **from** argument) is itself by definition. If the predecessor is zero, it means that the given vertex was not reached from the source during the search. Note that the search terminates if all the vertices in **to** are reached.

**inbound.edges**
Logical scalar, whether to return the inbound edge for each vertex. The inbound edge of vertex \( i \) in the tree is the edge via which vertex \( i \) was reached. The start vertex and vertices that were not reached during the search will have zero in the corresponding entry of the vector. Note that the search terminates if all the vertices in **to** are reached.

**directed**
Whether to consider directed paths in directed graphs, this argument is ignored for undirected graphs.

**unconnected**
What to do if the graph is unconnected (not strongly connected if directed paths are considered). If TRUE only the lengths of the existing paths are considered.
and averaged; if FALSE the length of the missing paths are counted having length `vcount(graph)`, one longer than the longest possible geodesic in the network.

Details

The shortest path, or geodesic between two pair of vertices is a path with the minimal number of vertices. The functions documented in this manual page all calculate shortest paths between vertex pairs.

`shortest.paths` calculates the lengths of pairwise shortest paths from a set of vertices (`from`) to another set of vertices (`to`). It uses different algorithms, depending on the `algorithm` argument and the `weight` edge attribute of the graph. The implemented algorithms are breadth-first search ("unweighted"), this only works for unweighted graphs; the Dijkstra algorithm ("dijkstra"), this works for graphs with non-negative edge weights; the Bellman-Ford algorithm ("bellman-ford"), and Johnson’s algorithm ("johnson"). The latter two algorithms work with arbitrary edge weights, but (naturally) only for graphs that don’t have a negative cycle.

`igraph` can choose automatically between algorithms, and chooses the most efficient one that is appropriate for the supplied weights (if any). For automatic algorithm selection, supply "automatic" as the `algorithm` argument. (This is also the default.)

`get.shortest.paths` calculates a single shortest path (i.e. the path itself, not just its length) between the source vertex given in `from`, to the target vertices given in `to`. `get.shortest.paths` uses breadth-first search for unweighted graphs and Dijkstra’s algorithm for weighted graphs. The latter only works if the edge weights are non-negative.

`get.all.shortest.paths` calculates all shortest paths between pairs of vertices. More precisely, between the `from` vertex to the vertices given in `to`. It uses a breadth-first search for unweighted graphs and Dijkstra’s algorithm for weighted ones. The latter only supports non-negative edge weights.

`average.path.length` calculates the average path length in a graph, by calculating the shortest paths between all pairs of vertices (both ways for directed graphs). This function does not consider edge weights currently and uses a breadth-first search.

`path.length.hist` calculates a histogram, by calculating the shortest path length between each pair of vertices. For directed graphs both directions are considered, so every pair of vertices appears twice in the histogram.

Value

For `shortest.paths` a numeric matrix with `length(to)` columns and `length(v)` rows. The shortest path length from a vertex to itself is always zero. For unreachable vertices `Inf` is included.

For `get.shortest.paths` a named list with four entries is returned:

`vpath` This itself is a list, of length `length(to)`: list element `i` contains the vertex ids on the path from `from` to vertex `to[i]` (or the other way for directed graphs depending on the `mode` argument). The vector also contains `from` and `i` as the first and last elements. If `from` is the same as `i` then it is only included once. If there is no path between two vertices then a numeric vector of length zero is returned as the list element. If this output is not requested in the `output` argument, then it will be `NULL`. 
epath
This is a list similar to vpath, but the vectors of the list contain the edge ids along the shortest paths, instead of the vertex ids. This entry is set to NULL if it is not requested in the output argument.

predecessors
Numeric vector, the predecessor of each vertex in the to argument, or NULL if it was not requested.

inbound_edges
Numeric vector, the inbound edge for each vertex, or NULL, if it was not requested.

For `get.all.shortest.paths` a list is returned, each list element contains a shortest path from `from` to a vertex in `to`. The shortest paths to the same vertex are collected into consecutive elements of the list.

For `average.path.length` a single number is returned.

`path.length.hist` returns a named list with two entries: `res` is a numeric vector, the histogram of distances, `unconnected` is a numeric scalar, the number of pairs for which the first vertex is not reachable from the second. The sum of the two entries is always $n(n-1)$ for directed graphs and $n(n-1)/2$ for undirected graphs.

**Examples**

```r
# Weighted shortest paths
el <- matrix(nc=3, byrow=TRUE,
            c(1,2,0, 1,3,2, 1,4,1, 2,3,0, 2,5,5, 2,6,2, 3,2,1, 3,4,1,
              3,7,1, 4,3,0, 4,7,2, 5,6,2, 5,8,8, 6,3,2, 6,7,1, 6,9,1,
              6,10,3, 8,6,1, 8,9,1, 9,10,4)

g2 <- add.edges(graph.empty(), t(el[,1:2]), weight=el[,3])
shortest.paths(g2, mode="out")
```

**similarity**

*Similarity measures of two vertices*

**Description**

These functions calculates similarity scores for vertices based on their connection patterns.
**Usage**

```python
similarity.jaccard(graph, vids = V(graph), mode = c("all", "out", "in", "total"), loops = FALSE)
similarity.dice(graph, vids = V(graph), mode = c("all", "out", "in", "total"), loops = FALSE)
similarity.invlogweighted(graph, vids = V(graph),
  mode = c("all", "out", "in", "total"))
```

**Arguments**

- **graph**: The input graph.
- **vids**: The vertex ids for which the similarity is calculated.
- **mode**: The type of neighboring vertices to use for the calculation, possible values: 'out', 'in', 'all'.
- **loops**: Whether to include vertices themselves in the neighbor sets.

**Details**

The Jaccard similarity coefficient of two vertices is the number of common neighbors divided by the number of vertices that are neighbors of at least one of the two vertices being considered. `similarity.jaccard` calculates the pairwise Jaccard similarities for some (or all) of the vertices.

The Dice similarity coefficient of two vertices is twice the number of common neighbors divided by the sum of the degrees of the vertices. `similarity.dice` calculates the pairwise Dice similarities for some (or all) of the vertices.

The inverse log-weighted similarity of two vertices is the number of their common neighbors, weighted by the inverse logarithm of their degrees. It is based on the assumption that two vertices should be considered more similar if they share a low-degree common neighbor, since high-degree common neighbors are more likely to appear even by pure chance. Isolated vertices will have zero similarity to any other vertex. Self-similarities are not calculated. See the following paper for more details: Lada A. Adamic and Eytan Adar: Friends and neighbors on the Web. Social Networks, 25(3):211-230, 2003.

**Value**

A `length(vids)` by `length(vids)` numeric matrix containing the similarity scores.

simplify

Simple graphs

Description

Simple graphs are graphs which do not contain loop and multiple edges.

Usage

simplify(graph, remove.multiple = TRUE, remove.loops = TRUE,
edge.attr.comb = getigraphOpt("edge.attr.comb"))
is.simple(graph)

Arguments

graph The graph to work on.
remove.loops Logical, whether the loop edges are to be removed.
remove.multiple Logical, whether the multiple edges are to be removed.
edge.attr.comb Specifies what to do with edge attributes, if remove.multiple=TRUE. In this
case many edges might be mapped to a single one in the new graph, and their
attributes are combined. Please see attribute.combination for details on this.

Details

A loop edge is an edge for which the two endpoints are the same vertex. Two edges are multiple
edges if they have exactly the same two endpoints (for directed graphs order does matter). A graph
is simple if it does not contain loop edges and multiple edges.
is.simple checks whether a graph is simple.
simplify removes the loop and/or multiple edges from a graph. If both remove.loops and remove.multiple
are TRUE the function returns a simple graph.

Value

A new graph object with the edges deleted.

**Author(s)**

is.simple(simplify(g, remove.loops=FALSE))
is.simple(simplify(g, remove.multiple=FALSE))
is.simple(simplify(g))
```

---

**sir**

*SIR model on graphs*

**Description**

Run simulations for an SIR (susceptible-infected-recovered) model, on a graph

**Usage**

```r
sir(graph, beta, gamma, no.sim=100)
```

## S3 method for class 'sir'

```r
time_bins(x, middle=TRUE)
```

## S3 method for class 'sir'

```r
median(x, na.rm=FALSE)
```

## S3 method for class 'sir'

```r
quantile(x, comp=c("NI", "NS", "NR"), prob, ...)
```

**Arguments**

- `graph` The graph to run the model on. If directed, then edge directions are ignored and a warning is given.
- `beta` Non-negative scalar. The rate of infection of an individual that is susceptible and has a single infected neighbor. The infection rate of a susceptible individual with n infected neighbors is n times beta. Formally this is the rate parameter of an exponential distribution.
- `gamma` Positive scalar. The rate of recovery of an infected individual. Formally, this is the rate parameter of an exponential distribution.
- `no.sim` Integer scalar, the number simulation runs to perform.
- `x` A `sir` object, returned by the `sir` function.
- `middle` Logical scalar, whether to return the middle of the time bins, or the boundaries.
Logical scalar, whether to ignore NA values. `sir` objects do not contain any NA values currently, so this argument is effectively ignored.

Character scalar. The component to calculate the quantile of. `NI` is infected agents, `NS` is susceptibles, `NR` stands for recovered.

Numeric vector of probabilities, in \([0,1]\), they specify the quantiles to calculate.

Additional arguments, ignored currently.

The SIR model is a simple model from epidemiology. The individuals of the population might be in three states: susceptible, infected and recovered. Recovered people are assumed to be immune to the disease. Susceptibles become infected with a rate that depends on their number of infected neighbors. Infected people become recovered with a constant rate.

The function `sir` simulates the model.

Function `time_bins` bins the simulation steps, using the Freedman-Diaconis heuristics to determine the bin width.

Function `median` and `quantile` calculate the median and quantiles of the results, respectively, in bins calculated with `time_bins`.

For `sir` the results are returned in an object of class `sir`, which is a list, with one element for each simulation. Each simulation is itself a list with the following elements. They are all numeric vectors, with equal length:

- `times` The times of the events.
- `NS` The number of susceptibles in the population, over time.
- `NI` The number of infected individuals in the population, over time.
- `NR` The number of recovered individuals in the population, over time.

Function `time_bins` returns a numeric vector, the middle or the boundaries of the time bins, depending on the `middle` argument.

`median` returns a list of three named numeric vectors, `NS`, `NI` and `NR`. The names within the vectors are created from the time bins.

`quantile` returns the same vector as `median` (but only one, the one requested) if only one quantile is requested. If multiple quantiles are requested, then a list of these vectors is returned, one for each quantile.

Gabor Csardi <csardi.gabor@gmail.com>. Eric Kolaczyk (http://math.bu.edu/people/kolaczyk/) wrote the initial version in R.

Spectral coarse graining

See Also

`plot.sir` to conveniently plot the results

Examples

G <- erdos.renyi.game(100, 100, type="gnm")
sm <- sir(G, beta=5, gamma=1)
plot(sm)
```

Spectral coarse graining

**Spectral Coarse Graining**

Description

Functions to perform the Spectral Coarse Graining (SCG) of matrices and graphs.

Introduction

The SCG functions provide a framework, called Spectral Coarse Graining (SCG), for reducing large graphs while preserving their spectral-related features, that is features closely related with the eigenvalues and eigenvectors of a graph matrix (which for now can be the adjacency, the stochastic, or the Laplacian matrix).

Common examples of such features comprise the first-passage-time of random walkers on Markovian graphs, thermodynamic properties of lattice models in statistical physics (e.g. Ising model), and the epidemic threshold of epidemic network models (SIR and SIS models).

SCG differs from traditional clustering schemes by producing a coarse-grained graph (not just a partition of the vertices), representative of the original one. As shown in [1], Principal Component Analysis can be viewed as a particular SCG, called exact SCG, where the matrix to be coarse-grained is the covariance matrix of some data set.

SCG should be of interest to practitioners of various fields dealing with problems where matrix eigenpairs play an important role, as for instance is the case of dynamical processes on networks.

SCG in brief

The main idea of SCG is to operate on a matrix a shrinkage operation specifically designed to preserve some of the matrix eigenpairs while not altering other important matrix features (such as its structure). Mathematically, this idea was expressed as follows. Consider a (complex) \( n \times n \) matrix \( M \) and form the product

\[
\tilde{M} = LMR^*,
\]

where \( \tilde{n} < n \) and \( L, R \in C^{\tilde{n} \times n} \) are such that \( LR^* = I_{\tilde{n}} \) \((R^* \) denotes the conjugate transpose of \( R \)). Under these assumptions, it can be shown that \( P = R^*L \) is an \( \tilde{n} \)-rank projector and that, if \((\lambda, v)\) is a (right) eigenpair of \( M \) (i.e. \( Mv = \lambda v \)) and \( P \) is orthogonal, there exists an eigenvalue \( \tilde{\lambda} \) of \( \tilde{M} \) such that

\[
|\lambda - \tilde{\lambda}| \leq \text{const} \|e_P(v)\| \left[1 + O(\|e_P(v)\|^2)\right],
\]
where \( \|e_P(v)\| = \|v - Pv\| \). Hence, if \( P \) (or equivalently \( L, R \)) is chosen so as to make \( \|e_P(v)\| \) as small as possible, one can preserve to any desired level the original eigenvalue \( \lambda \) in the coarse-grained matrix \( \tilde{M} \); under extra assumptions on \( M \), this result can be generalized to eigenvectors [1]. This leads to the following generic definition of a SCG problem.

Given \( M \in \mathbb{C}^{n \times n} \) and \((\lambda,v)\) a (right) eigenpair of \( M \) to be preserved by the coarse graining, the problem is to find a projector \( \hat{P} \) solving

\[
\min_{P \in \Omega} \|e_P(v)\|,
\]

where \( \Omega \) is a set of projectors in \( \mathbb{C}^{n \times n} \) described by some ad hoc constraints \( c_1, \ldots, c_r \) (e.g. \( c_1 : P \in \mathbb{R}^{n \times n}, c_2 : P = P^t, c_3 : P_{ij} \geq 0, \) etc).

Choosing pertinent constraints to solve the SCG problem is of great importance in applications. For instance, in the absence of constraints the SCG problem is solved trivially by \( \hat{P} = vv^* \) (\( v \) is assumed normalized). We have designed a particular constraint, called homogeneous mixing, which ensures that vertices belonging to the same group are merged consistently from a physical point of view (see [1] for details). Under this constraint the SCG problem reduces to finding the partition of \( \{1, \ldots, n\} \) (labeling the original vertices) minimizing

\[
\|e_P(v)\|^2 = \sum_{\alpha=1}^{n} \sum_{i \in \alpha} [v(i) - (Pv)(i)]^2,
\]

where \( \alpha \) denotes a group (i.e. a block) in a partition of \( \{1, \ldots, n\} \), and \( |\alpha| \) is the number of elements in \( \alpha \).

If \( M \) is symmetric or stochastic, for instance, then it may be desirable (or mandatory) to choose \( L, R \) so that \( \tilde{M} \) is symmetric or stochastic as well. This structural constraint has led to the construction of particular semi-projectors for symmetric [1], stochastic [3] and Laplacian [2] matrices, that are made available.

In short, the coarse graining of matrices and graphs involves:

1. Retrieving a matrix or a graph matrix \( M \) from the problem.
2. Computing the eigenpairs of \( M \) to be preserved in the coarse-grained graph or matrix.
3. Setting some problem-specific constraints (e.g. dimension of the coarse-grained object).
4. Solving the constrained SCG problem, that is finding \( \hat{P} \).
5. Computing from \( \hat{P} \) two semi-projectors \( \hat{L} \) and \( \hat{R} \) (e.g. following the method proposed in [1]).
6. Working out the product \( \tilde{M} = \hat{L}M\hat{R}^* \) and, if needed, defining from \( \tilde{M} \) a coarse-grained graph.

**Functions for performing SCG**

The main function is the “all-in-one” \texttt{scg}. This function handles all the steps involved in the Spectral Coarse Graining (SCG) of some particular matrices and graphs as described above and in reference [1]. In more details, \texttt{scg} computes some prescribed eigenpairs of a matrix or a graph matrix (for now adjacency, Laplacian and stochastic matrices are available), works out an optimal partition to preserve the eigenpairs, and finally outputs a coarse-grained matrix or graph along with other useful information.
These steps can also be carried out independently: (1) Use `get.adjacency`, `graph.laplacian` or `get.stochastic` to compute a matrix $M$. (2) Work out some prescribed eigenpairs of $M$ e.g. by means of eigen or arpack. (3) Invoke one the four algorithms of the function `scgGrouping` to get a partition that will preserve the eigenpairs in the coarse-grained matrix. (4) Compute the semi-projectors $L$ and $R$ using `scgSemiProjectors` and from there the coarse-grained matrix $\tilde{M} = LMR^*$. If necessary, construct a coarse-grained graph from $\tilde{M}$ (e.g. as in [1]).

**spinglass.community**

Finding communities in graphs based on statistical meachanics

**Description**

This function tries to find communities in graphs via a spin-glass model and simulated annealing.

**Usage**

```r
spinglass.community(graph, weights=NULL, vertex=NULL, spins=25, 
parupdate=FALSE, start.temp=1, stop.temp=0.01, 
cool.fact=0.99, update.rule=c("config", "random", 
"simple"), gamma=1, implementation=c("orig", "neg"), 
gamma.minus=1)
```

**Arguments**

- **graph**: The input graph, can be directed but the direction of the edges is neglected.
- **weights**: The weights of the edges. Either a numeric vector or NULL. If it is null and the input graph has a ‘weight’ edge attribute then that will be used. If NULL and no such attribute is present then the edges will have equal weights. Set this to NA if the graph was a ‘weight’ edge attribute, but you don’t want to use it for community detection.
- **vertex**: This parameter can be used to calculate the community of a given vertex without calculating all communities. Note that if this argument is present then some other arguments are ignored.
spins

Integer constant, the number of spins to use. This is the upper limit for the number of communities. It is not a problem to supply a (reasonably) big number here, in which case some spin states will be unpopulated.

parupdate

Logical constant, whether to update the spins of the vertices in parallel (synchronously) or not. This argument is ignored if the second form of the function is used (i.e. the ‘vertex’ argument is present). It is also not implemented in the “neg” implementation.

start.temp

Real constant, the start temperature. This argument is ignored if the second form of the function is used (i.e. the ‘vertex’ argument is present).

stop.temp

Real constant, the stop temperature. The simulation terminates if the temperature lowers below this level. This argument is ignored if the second form of the function is used (i.e. the ‘vertex’ argument is present).

cool.fact

Cooling factor for the simulated annealing. This argument is ignored if the second form of the function is used (i.e. the ‘vertex’ argument is present).

update.rule

Character constant giving the ‘null-model’ of the simulation. Possible values: “simple” and “config”. “simple” uses a random graph with the same number of edges as the baseline probability and “config” uses a random graph with the same vertex degrees as the input graph.

gamma

Real constant, the gamma argument of the algorithm. This specifies the balance between the importance of present and non-present edges in a community. Roughly, a community is a set of vertices having many edges inside the community and few edges outside the community. The default 1.0 value makes existing and non-existing links equally important. Smaller values make the existing links, greater values the missing links more important.

implementation

Character scalar. Currently igraph contains two implementations for the Spin-glass community finding algorithm. The faster original implementation is the default. The other implementation, that takes into account negative weights, can be chosen by supplying ‘neg’ here.

gamma.minus

Real constant, the gamma.minus parameter of the algorithm. This specifies the balance between the importance of present and non-present negative weighted edges in a community. Smaller values of gamma.minus, leads to communities with lesser negative intra-connectivity. If this argument is set to zero, the algorithm reduces to a graph coloring algorithm, using the number of spins as the number of colors. This argument is ignored if the ‘orig’ implementation is chosen.

Details

This function tries to find communities in a graph. A community is a set of nodes with many edges inside the community and few edges between outside it (i.e. between the community itself and the rest of the graph.)

This idea is reversed for edges having a negative weight, i.e. few negative edges inside a community and many negative edges between communities. Note that only the ‘neg’ implementation supports negative edge weights.

The spinglass.community function can solve two problems related to community detection. If the vertex argument is not given (or it is NULL), then the regular community detection problem is
solved (approximately), i.e. partitioning the vertices into communities, by optimizing the an energy function.

If the vertex argument is given and it is not NULL, then it must be a vertex id, and the same energy function is used to find the community of the the given vertex. See also the examples below.

Value

If the vertex argument is not given, ie. the first form is used then a `spinglass.community` returns a `communities` object.

If the vertex argument is present, ie. the second form is used then a named list is returned with the following components:

- `community` Numeric vector giving the ids of the vertices in the same community as vertex.
- `cohesion` The cohesion score of the result, see references.
- `adhesion` The adhesion score of the result, see references.
- `inner.links` The number of edges within the community of vertex.
- `outer.links` The number of edges between the community of vertex and the rest of the graph.

  spinglass.community(g, vertex=1)
```
srand

Set random seed of the C library's RNG

Description

Set the random seed of the C library’s RNG, for a new sequence of pseudo-random numbers.

Usage

srand(seed)

Arguments

seed Numeric scalar, the new random seed. It must be non-negative and will be converted to an integer.

Details

Note that this function has nothing to do with R’s random number generator, see set.seed for that.

Some package (e.g. ngspatial) use internal C code and generate random numbers using the standard C library’s built-in random number generator instead of using R’s RNGs. The srand function is provided to set the random seed for these packages. It simply calls the standard C function srand, with the supplied integer seed value.

Note that the standard C library’s RNGs are typically of very bad quality, and also slower than R’s RNGs. It is not worth using them, really, other than taking over some legacy C code that already uses them, and that would be difficult to rewrite to use R’s RNGs.

Value

NULL, invisibly.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

Description

This function generates a non-growing random graph with edge probabilities proportional to node fitness scores.
Usage

\texttt{static.fitness.game} (no.of.edges, fitness.out, fitness.in,
loops = FALSE, multiple = FALSE)

Arguments

- \textbf{no.of.edges} The number of edges in the generated graph.
- \textbf{fitness.out} A numeric vector containing the fitness of each vertex. For directed graphs, this specifies the out-fitness of each vertex.
- \textbf{fitness.in} If \texttt{NULL} (the default), the generated graph will be undirected. If not \texttt{NULL}, then it should be a numeric vector and it specifies the in-fitness of each vertex. If this argument is not \texttt{NULL}, then a directed graph is generated, otherwise an undirected one.
- \textbf{loops} Logical scalar, whether to allow loop edges in the graph.
- \textbf{multiple} Logical scalar, whether to allow multiple edges in the graph.

Details

This game generates a directed or undirected random graph where the probability of an edge between vertices \(i\) and \(j\) depends on the fitness scores of the two vertices involved. For undirected graphs, each vertex has a single fitness score. For directed graphs, each vertex has an out- and an in-fitness, and the probability of an edge from \(i\) to \(j\) depends on the out-fitness of vertex \(i\) and the in-fitness of vertex \(j\).

The generation process goes as follows. We start from \(N\) disconnected nodes (where \(N\) is given by the length of the fitness vector). Then we randomly select two vertices \(i\) and \(j\), with probabilities proportional to their fitnesses. (When the generated graph is directed, \(i\) is selected according to the out-fitnesses and \(j\) is selected according to the in-fitnesses). If the vertices are not connected yet (or if multiple edges are allowed), we connect them; otherwise we select a new pair. This is repeated until the desired number of links are created.

It can be shown that the expected degree of each vertex will be proportional to its fitness, although the actual, observed degree will not be. If you need to generate a graph with an exact degree sequence, consider \texttt{degree.sequence.game} instead.

This model is commonly used to generate static scale-free networks. To achieve this, you have to draw the fitness scores from the desired power-law distribution. Alternatively, you may use \texttt{static.power.law.game} which generates the fitnesses for you with a given exponent.

Value

An igraph graph, directed or undirected.

Author(s)

Tamas Nepusz <ntamas@gmail.com>
References

Examples

```r
N <- 10000
g <- static.power.law.game(5*N, sample((1:50)^-2, N, replace=TRUE))
degree.distribution(g)
## Not run: plot(degree.distribution(g, cumulative=TRUE), log="xy")
```

---

static.power.law.game  *Scale-free random graphs, from vertex fitness scores*

Description

This function generates a non-growing random graph with expected power-law degree distributions.

Usage

```r
static.power.law.game (no.of.nodes, no.of.edges, exponent.out,
            exponent.in = -1, loops = FALSE,
            multiple = FALSE, finite.size.correction = TRUE)
```

Arguments

- `no.of.nodes`  The number of vertices in the generated graph.
- `no.of.edges`  The number of edges in the generated graph.
- `exponent.out` Numeric scalar, the power law exponent of the degree distribution. For directed graphs, this specifies the exponent of the out-degree distribution. It must be greater than or equal to 2. If you pass `Inf` here, you will get back an Erdos-Renyi random network.
- `exponent.in`  Numeric scalar. If negative, the generated graph will be undirected. If greater than or equal to 2, this argument specifies the exponent of the in-degree distribution. If non-negative but less than 2, an error will be generated.
- `loops`  Logical scalar, whether to allow loop edges in the generated graph.
- `multiple`  Logical scalar, whether to allow multiple edges in the generated graph.
- `finite.size.correction`  Logical scalar, whether to use the proposed finite size correction of Cho et al., see references below.
Details

This game generates a directed or undirected random graph where the degrees of vertices follow power-law distributions with prescribed exponents. For directed graphs, the exponents of the in- and out-degree distributions may be specified separately.

The game simply uses `static.fitness.game` with appropriately constructed fitness vectors. In particular, the fitness of vertex $i$ is $i^{-\alpha}$, where $\alpha = 1/(\gamma - 1)$ and $\gamma$ is the exponent given in the arguments.

To remove correlations between in- and out-degrees in case of directed graphs, the in-fitness vector will be shuffled after it has been set up and before `static.fitness.game` is called.

Note that significant finite size effects may be observed for exponents smaller than 3 in the original formulation of the game. This function provides an argument that lets you remove the finite size effects by assuming that the fitness of vertex $i$ is $(i + i_0 - 1)^{-\alpha}$ where $i_0$ is a constant chosen appropriately to ensure that the maximum degree is less than the square root of the number of edges times the average degree; see the paper of Chung and Lu, and Cho et al for more details.

Value

An igraph graph, directed or undirected.

Author(s)

Tamas Nepusz <ntamas@gmail.com>

References

Examples

```r

g <- static.power.law.game(10000, 30000, 2.2, 2.3)
## Not run: plot(degree.distribution(g, cumulative=TRUE, mode="out"), log="xy")

stCuts
```

### List all (s,t)-cuts of a graph

Description

List all (s,t)-cuts in a directed graph.
Usage

stCuts(graph, source, target)

Arguments

graph The input graph. It must be directed.
source The source vertex.
target The target vertex.

Details

Given a $G$ directed graph and two, different and non-adjacent vertices, $s$ and $t$, an $(s,t)$-cut is a set of edges, such that after removing these edges from $G$ there is no directed path from $s$ to $t$.

Value

A list with entries:

cuts A list of numeric vectors containing edge ids. Each vector is an $(s,t)$-cut.
partitionQs A list of numeric vectors containing vertex ids, they correspond to the edge cuts. Each vertex set is a generator of the corresponding cut, i.e. in the graph $G = (V,E)$, the vertex set $X$ and its complementer $V - X$, generates the cut that contains exactly the edges that go from $X$ to $V - X$.

stMincuts to list all minimum cuts.

Examples

# A very simple graph
g <- graph.formula(a -> b, c, d, e)
stCuts(g, source="a", target="e")

# A somewhat more difficult graph
g2 <- graph.formula(s -> a:b, a:b, a -> t, 1:2:3, 1:2:3, b)
stCuts(g2, source="s", target="t")
**stMincuts**

*List all minimum (s, t)-cuts of a graph*

**Description**

Listing all minimum (s, t)-cuts of a directed graph, for given s and t.

**Usage**

`stMincuts(graph, source, target, capacity = NULL)`

**Arguments**

- **graph**: The input graph. It must be directed.
- **source**: The id of the source vertex.
- **target**: The id of the target vertex.
- **capacity**: Numeric vector giving the edge capacities. If this is `NULL` and the graph has a `weight` edge attribute, then this attribute defines the edge capacities. For forcing unit edge capacities, even for graphs that have a `weight` edge attribute, supply `NA` here.

**Details**

Given a G directed graph and two, different and non-adjacent vertices, s and t, an (s, t)-cut is a set of edges, such that after removing these edges from G there is no directed path from s to t.

The size of an (s, t)-cut is defined as the sum of the capacities (or weights) in the cut. For unweighed (=equally weighted) graphs, this is simply the number of edges.

An (s, t)-cut is minimum if it is of the smallest possible size.

**Value**

A list with entries:

- **value**: Numeric scalar, the size of the minimum cut(s).
- **cuts**: A list of numeric vectors containing edge ids. Each vector is a minimum (s, t)-cut.
- **partitionQs**: A list of numeric vectors containing vertex ids, they correspond to the edge cuts. Each vertex set is a generator of the corresponding cut, i.e. in the graph $G = (V, E)$, the vertex set $X$ and its complementer $V - X$, generates the cut that contains exactly the edges that go from $X$ to $V - X$.

Examples

```r
# A difficult graph, from the Provan-Shier paper

g <- graph.formula(s --- a:b, a:b --- t,
                    a --- 1:2:3:4:5, 1:2:3:4:5 --- b)

stMincuts(g, source="s", target="t")
```

structure.info  

Gaining information about graph structure

Description

Functions for exploring the basic structure of a network: number of vertices and edges, the neighbors of a node, test whether two vertices are connected by an edge.

Usage

```r
vcount(graph)
ecount(graph)
neighbors(graph, v, mode = c("out", "in", "all", "total"))
incident(graph, v, mode=c("all", "out", "in", "total"))
is.directed(graph)
are.connected(graph, v1, v2)
get.edge(graph, id)
get.edges(graph, es)
```

Arguments

- **graph**
  - The graph.

- **v**
  - The vertex of which the adjacent vertices or incident edges are queried.

- **mode**
  - Character string, specifying the type of adjacent vertices or incident edges to list in a directed graph. If “out”, then only outgoing edges (or their corresponding vertices) are considered; “in” considers incoming edges; “all” ignores edge directions. This argument is ignored for undirected graphs.

- **v1**
  - The id of the first vertex. For directed graphs only edges pointing from v1 to v2 are searched.

- **v2**
  - The id of the second vertex. For directed graphs only edges pointing from v1 to v2 are searched.

- **id**
  - A numeric edge id.

- **es**
  - An edge sequence.
Details

These functions provide the basic structural information of a graph.

\texttt{vcount} gives the number of vertices in the graph.
\texttt{ecount} gives the number of edges in the graph.
\texttt{neighbors} gives the neighbors of a vertex. The vertices connected by multiple edges are listed as many times as the number of connecting edges.
\texttt{incident} gives the incident edges of a vertex.
\texttt{is.directed} gives whether the graph is directed or not. It just gives its \texttt{directed} attribute.
\texttt{are.connected} decides whether there is an edge from $v_1$ to $v_2$.
\texttt{get.edge} returns the end points of the edge with the supplied edge id. For directed graph the source vertex comes first, for undirected graphs, the order is arbitrary.
\texttt{get.edges} returns a matrix with the endpoints of the edges in the edge sequence argument.

Value

\texttt{vcount} and \texttt{ecount} return integer constants. \texttt{neighbors} returns an integer vector. \texttt{is.directed} and \texttt{are.connected} return boolean constants. \texttt{get.edge} returns a numeric vector of length two. \texttt{get.edges} returns a two-column matrix.

are.connected(g, 2, 4)
get.edges(g, 1:5)
\end{verbatim}
subgraph

Subgraph of a graph

Description
subgraph creates a subgraph of a graph, containing only the specified vertices and all the edges among them.

Usage
induced.subgraph(graph, vids, impl=c("auto", "copy_and_delete", "create_from_scratch"))
subgraph.edges(graph, eids, delete.vertices = TRUE)
subgraph(graph, v)

Arguments
graph
The original graph.
vids,v
Numeric vector, the vertices of the original graph which will form the subgraph.
impl
Character scalar, to choose between two implementation of the subgraph calculation. ‘copy_and_delete’ copies the graph first, and then deletes the vertices and edges that are not included in the result graph. ‘create_from_scratch’ searches for all vertices and edges that must be kept and then uses them to create the graph from scratch. ‘auto’ chooses between the two implementations automatically, using heuristics based on the size of the original and the result graph.
eids
The edge ids of the edges that will be kept in the result graph.
delete.vertices
Logical scalar, whether to remove vertices that do not have any adjacent edges in eids.

Details
induced.subgraph calculates the induced subgraph of a set of vertices in a graph. This means that exactly the specified vertices and all the edges between them will be kept in the result graph.
subgraph.edges calculates the subgraph of a graph. For this function one can specify the vertices and edges to keep. This function will be renamed to subgraph in the next major version of igraph.
The subgraph function does the same as induced.graph currently (assuming ‘auto’ as the impl argument), but it is deprecated and will be removed in the next major version of igraph.

Value
A new graph object.
subgraph.centrality

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

Examples

```r
g <- graph.ring(10)
g2 <- induced.subgraph(g, 1:7)
g3 <- subgraph.edges(g, 1:5, 1:5)
```

Description

Subgraph centrality of a vertex measures the number of subgraphs a vertex participates in, weighting them according to their size.

Usage

```r
subgraph.centrality (graph, diag=FALSE)
```

Arguments

- `graph`: The input graph, it should be undirected, but the implementation does not check this currently.
- `diag`: Boolean scalar, whether to include the diagonal of the adjacency matrix in the analysis. Giving FALSE here effectively eliminates the loops edges from the graph before the calculation.

Details

The subgraph centrality of a vertex is defined as the number of closed loops originating at the vertex, where longer loops are exponentially downweighted.

Currently the calculation is performed by explicitly calculating all eigenvalues and eigenvectors of the adjacency matrix of the graph. This effectively means that the measure can only be calculated for small graphs.

Value

A numeric vector, the subgraph centrality scores of the vertices.

tkplot for interactive plotting of graphs.
**tkplot**

*Interactive plotting of graphs*

**Description**

tkplot and its companion functions serve as an interactive graph drawing facility. Not all parameters of the plot can be changed interactively right now though, eg. the colors of vertices, edges, and also others have to be pre-defined.

**Usage**

```
tkplot(graph, canvas.width=450, canvas.height=450, ...)

tkplot.close(tkp.id, window.close = TRUE)
tkplot.off()
tkplot.fit.to.screen(tkp.id, width = NULL, height = NULL)
tkplot.reshape(tkp.id, newlayout, ...)
tkplot.export.postscript(tkp.id)
tkplot.canvas(tkp.id)
tkplot.getcoords(tkp.id, norm = FALSE)
tkplot.setcoords(tkp.id, coords)
tkplot.center(tkp.id)
tkplot.rotate(tkp.id, degree = NULL, rad = NULL)
```

**Arguments**

- **graph** The graph to plot.
- **canvas.width, canvas.height** The size of the tkplot drawing area.
- **tkp.id** The id of the tkplot window to close/reshape/etc.
- **window.close** Leave this on the default value.
- **width** The width of the rectangle for generating new coordinates.
- **height** The height of the rectangle for generating new coordinates.
- **newlayout** The new layout, see the layout parameter of tkplot.
- **norm** Logical, should we norm the coordinates.
- **coords** Two-column numeric matrix, the new coordinates of the vertices, in absolute coordinates.
- **degree** The degree to rotate the plot.
- **rad** The degree to rotate the plot, in radian.
- **...** Additional plotting parameters. See igraph.plotting for the complete list.
Details

**tkplot** is an interactive graph drawing facility. It is not very well developed at this stage, but it should be still useful.

It’s handling should be quite straightforward most of the time, here are some remarks and hints.

There are different popup menus, activated by the right mouse button, for vertices and edges. Both operate on the current selection if the vertex/edge under the cursor is part of the selection and operate on the vertex/edge under the cursor if it is not.

One selection can be active at a time, either a vertex or an edge selection. A vertex/edge can be added to a selection by holding the control key while clicking on it with the left mouse button. Doing this again deselect the vertex/edge.

Selections can be made also from the Select menu. The ‘Select some vertices’ dialog allows to give an expression for the vertices to be selected: this can be a list of numeric R expressions separated by commas, like ‘1,2:10,12,14,15’ for example. Similarly in the ‘Select some edges’ dialog two such lists can be given and all edges connecting a vertex in the first list to one in the second list will be selected.

In the color dialog a color name like ‘orange’ or RGB notation can also be used.

The **tkplot** command creates a new Tk window with the graphical representation of the graph. The command returns an integer number, the tkplot id. The other commands utilize this id to be able to query or manipulate the plot.

**tkplot.close** closes the Tk plot with id tkp.id.

**tkplot.off** closes all Tk plots.

**tkplot.fit.to.screen** fits the plot to the given rectangle (width and height), if some of these are NULL the actual physical width or height of the plot window is used.

**tkplot.reshape** applies a new layout to the plot, its optional parameters will be collected to a list analogous to layout.par.

**tkplot.export.postscript** creates a dialog window for saving the plot in postscript format.

**tkplot.canvas** returns the Tk canvas object that belongs to a graph plot. The canvas can be directly manipulated then, eg. labels can be added, it could be saved to a file programmatically, etc. See an example below.

**tkplot.getcoords** returns the coordinates of the vertices in a matrix. Each row corresponds to one vertex.

**tkplot.setcoords** sets the coordinates of the vertices. A two-column matrix specifies the new positions, with each row corresponding to a single vertex.

**tkplot.center** shifts the figure to the center of its plot window.

**tkplot.rotate** rotates the figure, its parameter can be given either in degrees or in radians.

**Value**

**tkplot** returns an integer, the id of the plot, this can be used to manipulate it from the command line.

**tkplot.canvas** returns tkwin object, the Tk canvas.

**tkplot.getcoords** returns a matrix with the coordinates.
tkplot.close, tkplot.off, tkplot.fit.to.screen, tkplot.reshape, tkplot.export.postscript, tkplot.center and tkplot.rotate return NULL invisibly.

         justify="center", font=tkfont.create(family="helvetica",
                                                  size=20, weight="bold"))

## End(Not run)
Description

A topological sorting of a directed acyclic graph is a linear ordering of its nodes where each node comes before all nodes to which it has edges.

Usage

topological.sort(graph, mode=c("out", "all", "in"))

Arguments

graph The input graph, should be directed
mode Specifies how to use the direction of the edges. For “out”, the sorting order ensures that each node comes before all nodes to which it has edges, so nodes with no incoming edges go first. For “in”, it is quite the opposite: each node comes before all nodes from which it receives edges. Nodes with no outgoing edges go first.

Details

Every DAG has at least one topological sort, and may have many. This function returns a possible topological sort among them. If the graph is not acyclic (it has at least one cycle), a partial topological sort is returned and a warning is issued.

Value

A numeric vector containing vertex ids in topologically sorted order.

Author(s)

Tamas Nepusz <ntamas@gmail.com> and Gabor Csardi <csardi.gabor@gmail.com> for the R interface

Examples

g <- barabasi.game(100)
topological.sort(g)
Graph generation based on different vertex types

Description

These functions implement evolving network models based on different vertex types.

Usage

callaway.traits.game (nodes, types, edge.per.step = 1, type.dist = rep(1, types), pref.matrix = matrix(1, types, types), directed = FALSE)
establishment.game(nodes, types, k = 1, type.dist = rep(1, types), pref.matrix = matrix(1, types, types), directed = FALSE)

Arguments

- **nodes**: The number of vertices in the graph.
- **types**: The number of different vertex types.
- **edge.per.step**: The number of edges to add to the graph per time step.
- **type.dist**: The distribution of the vertex types. This is assumed to be stationary in time.
- **pref.matrix**: A matrix giving the preferences of the given vertex types. These should be probabilities, i.e. numbers between zero and one.
- **directed**: Logical constant, whether to generate directed graphs.
- **k**: The number of trials per time step, see details below.

Details

For callaway.traits.game the simulation goes like this: in each discrete time step a new vertex is added to the graph. The type of this vertex is generated based on type.dist. Then two vertices are selected uniformly randomly from the graph. The probability that they will be connected depends on the types of these vertices and is taken from pref.matrix. Then another two vertices are selected and this is repeated edge.per.step times in each time step.

For establishment.game the simulation goes like this: a single vertex is added at each time step. This new vertex tries to connect to k vertices in the graph. The probability that such a connection is realized depends on the types of the vertices involved and is taken from pref.matrix.

Value

A new graph object.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>
Examples

# two types of vertices, they like only themselves

g1 <- callaway.traits.game(1000, 2, pref.matrix=matrix(c(1,0,0,1), nc=2))
g2 <- establishment.game(1000, 2, k=2, pref.matrix=matrix(c(1,0,0,1), nc=2))

transitivity

Transitivity of a graph

Description

Transitivity measures the probability that the adjacent vertices of a vertex are connected. This is sometimes also called the clustering coefficient.

Usage

transitivity(graph, type=c("undirected", "global", "globalundirected", "localundirected", "local", "average", "localaverage", "localaverageundirected", "barrat", "weighted"), vids=NULL, weights=NULL, isolates=c("NaN", "zero"))

Arguments

graph The graph to analyze.
type The type of the transitivity to calculate. Possible values:

  global The global transitivity of an undirected graph (directed graphs are considered as undirected ones as well). This is simply the ratio of the triangles and the connected triples in the graph. For directed graph the direction of the edges is ignored.

  local The local transitivity of an undirected graph, this is calculated for each vertex given in the vids argument. The local transitivity of a vertex is the ratio of the triangles connected to the vertex and the triples centered on the vertex. For directed graph the direction of the edges is ignored.

  undirected This is the same as global.

  globalundirected This is the same as global.

  localundirected This is the same as local.

  barrat The weighted transitivity as defined A. Barrat. See details below.

  weighted The same as barrat.

vids The vertex ids for the local transitivity will be calculated. This will be ignored for global transitivity types. The default value is NULL, in this case all vertices are considered. It is slightly faster to supply NULL here than V(graph).

weights Optional weights for weighted transitivity. It is ignored for other transitivity measures. If it is NULL (the default) and the graph has a weight edge attribute, then it is used automatically.
isolates

Character scalar, defines how to treat vertices with degree zero and one. If it
is ‘NaN’ then they local transitivity is reported as NaN and they are not included
in the averaging, for the transitivity types that calculate an average. If there are
no vertices with degree two or higher, then the averaging will still result NaN. If
it is ‘zero’, then we report 0 transitivity for them, and they are included in the
averaging, if an average is calculated.

Details

Note that there are essentially two classes of transitivity measures, one is a vertex-level, the other a
graph level property.

There are several generalizations of transitivity to weighted graphs, here we use the definition by
A. Barrat, this is a local vertex-level quantity, its formula is

\[ C_i^w = \frac{1}{s_i(k_i - 1)} \sum_{j,h} \frac{w_{ij} + w_{ih}}{2} a_{ij}a_{ih}a_{jh} \]

s_i is the strength of vertex i, see graph.strength, a_{ij} are elements of the adjacency matrix, k_i is
the vertex degree, w_{ij} are the weights.

This formula gives back the normal not-weighted local transitivity if all the edge weights are the
same.

The \texttt{barrat} type of transitivity does not work for graphs with multiple and/or loop edges. If you
want to calculate it for a directed graph, call \texttt{as.undirected} with the collapse mode first.

Value

For ‘global’ a single number, or NaN if there are no connected triples in the graph.
For ‘local’ a vector of transitivity scores, one for each vertex in ‘vids’.

triad.census

Triad census, subgraphs with three vertices

Description

This function counts the different subgraphs of three vertices in a graph.

Usage

triad.census(graph)

Arguments

graph

The input graph, it should be directed. An undirected graph results a warning, and undefined results.

Details

Triad census was defined by David and Leinhardt (see References below). Every triple of vertices (A, B, C) are classified into the 16 possible states:

- **003**: A,B,C, the empty graph.
- **012**: A->B, C, the graph with a single directed edge.
- **102**: A<->B, C, the graph with a mutual connection between two vertices.
- **021D**: A<->B>C, the out-star.
- **021U**: A->B<->C, the in-star.
- **021C**: A->B->C, directed line.
- **111D**: A<->B<->C.
- **111U**: A<->B>C.
- **030T**: A->B<->C, A->C.
- **030C**: A->B<->C, A->C.
- **201**: A<->B<->C.
120D  A<-B->C, A<->C.
120U  A->B<-C, A<->C.
120C  A->B->C, A<->C.
210   A->B<->C, A<->C.
300   A<->B<->C, A<->C, the complete graph.

This function uses the RANDESU motif finder algorithm to find and count the subgraphs, see graph.motifs.

Value

A numeric vector, the subgraph counts, in the order given in the above description.

unfold.tree  

Convert a general graph into a forest

Description

Perform a breadth-first search on a graph and convert it into a tree or forest by replicating vertices that were found more than once.

Usage

unfold.tree(graph, mode = c("all", "out", "in", "total"), roots)
Arguments

- **graph**: The input graph, it can be either directed or undirected.
- **mode**: Character string, defined the types of the paths used for the breadth-first search. “out” follows the outgoing, “in” the incoming edges, “all” and “total” both of them. This argument is ignored for undirected graphs.
- **roots**: A vector giving the vertices from which the breadth-first search is performed. Typically it contains one vertex per component.

Details

A forest is a graph, whose components are trees.

The roots vector can be calculated by simply doing a topological sort in all components of the graph, see the examples below.

Value

A list with two components:

- **tree**: The result, an igraph object, a tree or a forest.
- **vertex_index**: A numeric vector, it gives a mapping from the vertices of the new graph to the vertices of the old graph.

Author(s)

Gabor Csardi <csardi.gabor@gmail.com>

Examples

```r
# Load igraph library
library(igraph)

# Create a tree with 10 vertices
g <- graph.tree(10)
V(g)$id <- seq_len(vcount(g))-1
roots <- sapply(decompose.graph(g), function(x) {
  V(x)$id[topological.sort(x)[1]+1]
})

# Unfold the tree
rooted <- unfold.tree(g, roots)
deep <- V(rooted)$id
```

---

### Vertex shapes

Various vertex shapes when plotting igraph graphs

Description

Starting from version 0.5.1 igraph supports different vertex shapes when plotting graphs.

Usage

```r
vertex.shapes (shape = NULL)
add.vertex.shape (shape, clip = igraph.shape.noclip, plot = igraph.shape.noplot, parameters = list())
igraph.shape.noclip (coords, el, params, end = c("both", "from", "to"))
igraph.shape.noplot (coords, v = NULL, params)
```
Vertex shapes

Arguments

- **shape**: Character scalar, name of a vertex shape. If it is NULL for `vertex.shapes`, then the names of all defined vertex shapes are returned.
- **clip**: An R function object, the clipping function.
- **plot**: An R function object, the plotting function.
- **parameters**: Named list, additional plot/vertex/edge parameters. The element named define the new parameters, and the elements themselves define their default values. Vertex parameters should have a prefix ‘vertex.’, edge parameters a prefix ‘edge.’. Other general plotting parameters should have a prefix ‘plot.’. See Details below.
- **coords, el, params, end, v**
  
  See parameters of the clipping/plotting functions below.

Details

In igraph a vertex shape is defined by two functions: 1) provides information about the size of the shape for clipping the edges and 2) plots the shape if requested. These functions are called “shape functions” in the rest of this manual page. The first one is the clipping function and the second is the plotting function.

The clipping function has the following arguments:

- **coords**: A matrix with four columns, it contains the coordinates of the vertices for the edge list supplied in the `el` argument.
- **el**: A matrix with two columns, the edges of which some end points will be clipped. It should have the same number of rows as `coords`.
- **params**: This is a function object that can be called to query vertex/edge/plot graphical parameters. The first argument of the function is “vertex”, “edge” or “plot” to decide the type of the parameter, the second is a character string giving the name of the parameter. E.g.

  ```r
  params("vertex", "size")
  ```

- **end**: Character string, it gives which end points will be used. Possible values are “both”, “from” and “to”. If “from” the function is expected to clip the first column in the `el` edge list, “to” selects the second column, “both” selects both.

The clipping function should return a matrix with the same number of rows as the `el` arguments. If `end` is `both` then the matrix must have four columns, otherwise two. The matrix contains the modified coordinates, with the clipping applied.

The plotting function has the following arguments:

- **coords**: The coordinates of the vertices, a matrix with two columns.
- **v**: The ids of the vertices to plot. It should match the number of rows in the `coords` argument.
- **params**: The same as for the clipping function, see above.

The return value of the plotting function is not used.
vertex.shapes can be used to list the names of all installed vertex shapes, by calling it without arguments, or setting the shape argument to NULL. If a shape name is given, then the clipping and plotting functions of that shape are returned in a named list.

add.vertex.shape can be used to add new vertex shapes to igraph. For this one must give the clipping and plotting functions of the new shape. It is also possible to list the plot/vertex/edge parameters, in the parameters argument, that the clipping and/or plotting functions can make use of. An example would be a generic regular polygon shape, which can have a parameter for the number of sides.

igraph.shape.noclip is a very simple clipping function that the user can use in their own shape definitions. It does no clipping, the edges will be drawn exactly until the listed vertex position coordinates.

igraph.shape.noplot is a very simple (and probably not very useful) plotting function, that does not plot anything.

Value

vertex.shapes returns a character vector if the shape argument is NULL. It returns a named list with entries named 'clip' and 'plot', both of them R functions.

add.vertex.shape returns TRUE, invisibly.

igraph.shape.noclip returns the appropriate columns of its coords argument.

igraph.shape.noplot returns NULL, invisibly.

vertex.connectivity  Vertex connectivity.

Description

The vertex connectivity of a graph or two vertices, this is recently also called group cohesion.

Usage

vertex.connectivity(graph, source=NULL, target=NULL, checks=TRUE)
vertex.disjoint.paths(graph, source, target)
graph.cohesion(graph, checks=TRUE)

Arguments

graph  The input graph.
source  The id of the source vertex, for vertex.connectivity it can be NULL, see details below.
target  The id of the target vertex, for vertex.connectivity it can be NULL, see details below.
checks  Logical constant. Whether to check that the graph is connected and also the degree of the vertices. If the graph is not (strongly) connected then the connectivity is obviously zero. Otherwise if the minimum degree is one then the vertex connectivity is also one. It is a good idea to perform these checks, as they can be done quickly compared to the connectivity calculation itself. They were suggested by Peter McMahan, thanks Peter.

Details

The vertex connectivity of two vertices (source and target) in a directed graph is the minimum number of vertices needed to remove from the graph to eliminate all (directed) paths from source to target. vertex.connectivity calculates this quantity if both the source and target arguments are given and they're not NULL.

The vertex connectivity of a graph is the minimum vertex connectivity of all (ordered) pairs of vertices in the graph. In other words this is the minimum number of vertices needed to remove to make the graph not strongly connected. (If the graph is not strongly connected then this is zero.) vertex.connectivity calculates this quantity if neither the source nor target arguments are given. (Ie. they are both NULL.)
A set of vertex disjoint directed paths from source to vertex is a set of directed paths between them whose vertices do not contain common vertices (apart from source and target). The maximum number of vertex disjoint paths between two vertices is the same as their vertex connectivity in most cases (if the two vertices are not connected by an edge).

The cohesion of a graph (as defined by White and Harary, see references), is the vertex connectivity of the graph. This is calculated by graph.cohesion.

These three functions essentially calculate the same measure(s), more precisely vertex.connectivity is the most general, the other two are included only for the ease of using more descriptive function names.

Value

A scalar real value.

graph.cohesion(G)
```
walktrap.community

Community strucure via short random walks

Description

This function tries to find densely connected subgraphs, also called communities in a graph via random walks. The idea is that short random walks tend to stay in the same community.

Usage

```r
walktrap.community(graph, weights = E(graph)$weight, steps = 4, merges = TRUE, modularity = TRUE, membership = TRUE)
```

Arguments

- **graph**: The input graph, edge directions are ignored in directed graphs.
- **weights**: The edge weights.
- **steps**: The length of the random walks to perform.
- **merges**: Logical scalar, whether to include the merge matrix in the result.
- **modularity**: Logical scalar, whether to include the vector of the modularity scores in the result. If the `membership` argument is true, then it will be always calculated.
- **membership**: Logical scalar, whether to calculate the membership vector for the split corresponding to the highest modularity value.

Details

This function is the implementation of the Walktrap community finding algorithm, see Pascal Pons, Matthieu Latapy: Computing communities in large networks using random walks, http://arxiv.org/abs/physics/0512106

Value

`walktrap.community` returns a `communities` object, please see the `communities` manual page for details.

Author(s)

Pascal Pons (http://psl.pons.free.fr/) and Gabor Csardi <csardi.gabor@gmail.com> for the R and igraph interface

Examples

```r
    g <- graph.full(5) %du% graph.full(5) %du% graph.full(5)
    g <- add.edges(g, c(1, 6, 1, 11, 6, 11))
    walktrap.community(g)
```

watts.strogatz.game  The Watts-Strogatz small-world model

Description

Generate a graph according to the Watts-Strogatz network model.

Usage

```
    watts.strogatz.game(dim, size, nei, p, loops = FALSE, multiple = FALSE)
```

Arguments

- `dim`  
  Integer constant, the dimension of the starting lattice.

- `size`  
  Integer constant, the size of the lattice along each dimension.

- `nei`  
  Integer constant, the neighborhood within which the vertices of the lattice will be connected.

- `p`  
  Real constant between zero and one, the rewiring probability.

- `loops`  
  Logical scalar, whether loops edges are allowed in the generated graph.

- `multiple`  
  Logical scalar, whether multiple edges are allowed in the generated graph.

Details

First a lattice is created with the given `dim`, `size` and `nei` arguments. Then the edges of the lattice are rewired uniformly randomly with probability `p`.

Note that this function might create graphs with loops and/or multiple edges. You can use `simplify` to get rid of these.

Value

- A graph object.

write.graph (Writing the graph to a file in some format)

Description

write.graph is a general function for exporting graphs to foreign file formats, however not many formats are implemented right now.

Usage

write.graph(graph, file, format=c("edgelist", "pajek", "ncol", "lgl", "graphml", "dimacs", "gml", "dot", "leda"), ...)

Arguments

graph The graph to export.
file A connection or a string giving the file name to write the graph to.
format Character string giving the file format. Right now pajek, graphml, dot, gml, edgelist, lgl, ncol and dimacs are implemented. As of igraph 0.4 this argument is case insensitive.
... Other, format specific arguments, see below.

Value

A NULL, invisibly.

Edge list format

The edgelist format is a simple text file, with one edge in a line, the two vertex ids separated by a space character. The file is sorted by the first and the second column. This format has no additional arguments.
Pajek format

The Pajek format is a text file, see `read.graph` for details. Appropriate vertex and edge attributes are also written to the file. This format has no additional arguments.

From version 0.6.1 igraph handles bipartite graphs when writing to Pajek files. As Pajek is less flexible for bipartite graphs (the numeric ids of the vertices must be sorted according to vertex type), igraph might need to reorder the vertices when writing a bipartite Pajek file. This effectively means that numeric vertex ids usually change when a bipartite graph is written to a Pajek file, and then read back into igraph.

GraphML format

The GraphML format is a flexible XML based format. See `read.graph` for GraphML details. Vertex and edge attributes are also written to the file. Additional argument:

prefixAttr Logical scalar, whether you want to add a prefix to the graph, vertex and edge attribute names, to ensure their uniqueness. Defaults to `TRUE`.

Dot format

The dot format is used by the popular GraphViz program. Vertex and edge attributes are written to the file. There are no additional arguments for this format.

LGL format

The lgl format is also a simple text file, this is the format expected by the 'Large Graph Layout' layout generator software. See `read.graph` for details. Additional arguments:

names If you want to write symbolic vertex names instead of vertex ids, supply the name of the vertex attribute containing the symbolic names here. By default the ‘name’ attribute is used if there is one. Supply `NULL` if you want to use numeric vertex ids even if there is a ‘name’ vertex attribute.

weights If you want to write edge weights to the file, supply the name of the edge attribute here. By defaults the vertex attribute ‘weights’ are used if they are installed. Supply `NULL` here if you want to omit the weights.

isolates Logical, if `TRUE` the isolate vertices are also written to the file, they are omitted by default.

NCOL format

The ncol format is also used by LGL, it is a text file, see `read.graph` for details. Additional arguments:

names If you want to write symbolic vertex names instead of vertex ids, supply the name of the vertex attribute containing the symbolic names here. By default the ‘name’ attribute is used if there is one. Supply `NULL` if you want to use numeric vertex ids even if there is a ‘name’ vertex attribute.

weights If you want to write edge weights to the file, supply the name of the edge attribute here. By defaults the vertex attribute ‘weights’ are used if they are installed. Supply `NULL` here if you want to omit the weights.
**Dimacs format**

The Dimacs file format, more specifically the version for network flow problems, see the files at ftp://dimacs.rutgers.edu/pub/netflow/general-info/

This is a line-oriented text file (ASCII) format. The first character of each line defines the type of the line. If the first character is c the line is a comment line and it is ignored. There is one problem line (p in the file, it must appear before any node and arc descriptor lines. The problem line has three fields separated by spaces: the problem type (min, max or asn), the number of vertices and number of edges in the graph. Exactly two node identification lines are expected (n), one for the source, one for the target vertex. These have two fields: the id of the vertex and the type of the vertex, either s (=source) or t (=target). Arc lines start with a and have three fields: the source vertex, the target vertex and the edge capacity.

Vertex ids are numbered from 1.

Additional arguments:

- **source** The id of the source vertex, if NULL (the default) then it is taken from the source graph attribute.
- **target** The id of the target vertex, if NULL (the default) then it is taken from the target graph attribute.
- **capacity** A numeric vector giving the edge capacities. If NULL (the default) then it is taken from the capacity edge attribute.

**GML file format**

GML is a quite general textual format, see http://www.infosun.fim.uni-passau.de/Graphlet/GML/ for details.

The graph, vertex and edges attributes are written to the file as well, if they are numeric or string.

As igraph is more forgiving about attribute names, it might be necessary to simplify them before writing to the GML file. This way we'll have a syntactically correct GML file. The following simple procedure is performed on each attribute name: first the alphanumeric characters are extracted, the others are ignored. Then if the first character is not a letter then the attribute name is prefixed with <quote>igraph</quote>. Note that this might result identical names for two attributes, igraph does not check this.

The “id” vertex attribute is treated specially. If the id argument is not NULL then it should be a numeric vector with the vertex ids and the “id” vertex attribute is ignored (if there is one). If id is 0 and there is a numeric id vertex attribute that is used instead. If ids are not specified in either way then the regular igraph vertex ids are used.

Note that whichever way vertex ids are specified, their uniqueness is not checked.

If the graph has edge attributes named “source” or “target” they’re silently ignored. GML uses these attributes to specify the edges, so we cannot write them to the file. Rename them before calling this function if you want to preserve them.

Additional arguments:

- **id** NULL or a numeric vector giving the vertex ids. See details above.
- **creator** A character scalar to be added to the “Creator” line in the GML file. If this is NULL (the default) then the current date and time is added.
LEDA file format

LEDA is a library for efficient data types and algorithms. The support for the LEDA format is very basic at the moment; igraph writes only the LEDA graph section which supports one selected vertex and edge attribute and no layout information or visual attributes. See http://www.algorithmic-solutions.info/leda_guide/graphs/leda_native_graph_fileformat.html for the details of this format.

Additional arguments:

vertex.attr The name of the vertex attribute whose values are to be stored in the output or NULL if no vertex attribute has to be stored.

edge.attr The name of the edge attribute whose values are to be stored in the output or NULL if no edge attribute has to be stored.
