Abstract

This vignette gives a brief overview of (some of) the functionality contained in \texttt{zoo} including several nifty code snippets when dealing with (daily) financial data. For a more complete overview of the package’s functionality and extensibility see Zeileis and Grothendieck (2005) (contained as vignette “zoo” in the package), the manual pages and the reference card.

Keywords: irregular time series, daily data, weekly data, returns.

**Read a series from a text file**

To read in data in a text file, \texttt{read.table()} and associated functions can be used as usual with \texttt{zoo()} being called subsequently. The convenience function \texttt{read.zoo} is a simple wrapper to these functions that assumes the index is in the first column of the file and the remaining columns are data.

Data in \texttt{demo1.txt}, where each row looks like

23 Feb 2005|43.72

can be read in via

\[
R> \text{Sys.setlocale("LC\_TIME", "C")}
\]

\[
[1] "C"
\]

\[
R> \text{inrusd} <- \text{read.zoo("demo1.txt", sep = ",", format="\%d \%b \%Y")}
\]

The \texttt{format} argument causes the first column to be transformed to an index of class "Date". The \texttt{Sys.setlocale} is set to "C" here to assure that the English month abbreviations are read correctly. (It is unnecessary if the system is already set to a locale that understands English month abbreviations.)

The data in \texttt{demo2.txt} look like

24 Feb 2005,2055.30,4337.00

daily,24 Feb 2005,2055.30,4337.00

and requires more attention because of the format of the first column.
**Query dates**

To return all dates corresponding to a series `index(z)` or equivalently

```r
R> time(z)
```

```r
[16] "2005-03-04" "2005-03-07" "2005-03-08" "2005-03-09" "2005-03-10"
```
can be used. The first and last date can be obtained by

```r
R> start(z)
```

```r
[1] "2005-02-10"
```

```r
R> end(inrusd)
```

```r
[1] "2005-03-10"
```

**Convert back into a plain matrix**

To strip off the dates and just return a plain vector/matrix `coredata` can be used

```r
R> plain <- coredata(z)
R> str(plain)
```

```r	num [1:20, 1:2] 2063 2082 2098 2090 2062 ...  
- attr(*, "dimnames")=List of 2  
  ..$: NULL  
  ..$: chr [1:2] "Nifty" "Junior"
```

**Union and intersection**

Unions and intersections of series can be computed by `merge`. The intersection are those days where both series have time points:

```r
R> m <- merge(inrusd, z, all = FALSE)
```

whereas the union uses all dates and fills the gaps where one series has a time point but the other does not with NAs (by default):
R> m <- merge(inrusd, z)

cbind(inrusd, z) is almost equivalent to the merge call, but may lead to inferior naming in some situations hence merge is preferred

To combine a series with its lag, use

R> merge(inrusd, lag(inrusd, -1))

Visualization

By default, the plot method generates a graph for each series in m

R> plot(m)
but several series can also be plotted in a single window.

\[ R> \text{plot(m[, 2:3], plot.type = "single", col = c("red", "blue"), lwd = 2)} \]
Select (a few) observations

Selections can be made for a range of dates of interest

\[
R> \text{window}(z, \text{start} = \text{as.Date}("2005-02-15"), \text{end} = \text{as.Date}("2005-02-28"))
\]

<table>

and others.

\textbf{Prices and returns}

To compute log-difference returns in %, the following convenience function is defined

\texttt{R} \> \texttt{prices2returns} \leftarrow \texttt{function(x) 100*diff(log(x))}

which can be used to convert all columns (of prices) into returns.

\texttt{R} \> \texttt{r} \leftarrow \texttt{prices2returns(m)}

A 10-day rolling window standard deviations (for all columns) can be computed by

\texttt{R} \> \texttt{rollapply(r, 10, sd)}

To go from a daily series to the series of just the last-traded-day of each month, `aggregate` can be used:

```r
R> prices2returns(aggregate(m, as.yearmon, tail, 1))
```

```
inrusd  Nifty   Junior
Mar 2005 -0.1375831 3.004453 5.752866
```

Analogously, the series can be aggregated to the last-traded-day of each week, employing a convenience function `nextfri` that computes for each "Date" the next friday.

```r
R> nextfri <- function(x) 7 * ceiling(as.numeric(x-5+4) / 7) + as.Date(5-4)
R> prices2returns(aggregate(na.locf(m), nextfri, tail, 1))
```

```
inrusd  Nifty   Junior
2005-02-18 0.11411618 -1.2809533 -1.4883536
2005-02-25 -0.34273997 0.2599329 -0.2875731
2005-03-04 0.04576659 4.1464226 5.5076988
2005-03-11 -0.29785794 0.8921286 2.1419450
```

Here is a similar example of `aggregate` where we define `to4sec` analogously to `nextfri` in order to aggregate the `zoo` object `zsec` every 4 seconds.

```r
R> zsec <- structure(1:10, index = structure(c(1234760403.968, 1234760403.969, 1234760405.029, 1234760405.03, 1234760405.03, 1234760405.073, 1234760405.073), class = c("POSIXt", "POSIXct"), tzone = ""), class = "zoo")
R> to4sec <- function(x) as.POSIXct(4*ceiling(as.numeric(x)/4), origin = "1970-01-01")
R> aggregate(zsec, to4sec, tail, 1)
```

```
2009-02-16 05:00:04 2009-02-16 05:00:08
3 10
```

Here is another example using the same `zsec` `zoo` object but this time rather than aggregating we truncate times to the second using the last data value for each such second. For large objects this will be much faster than using `aggregate.zoo`.

```r
R> # tmp is zsec with time discretized into one second bins
R> tmp <- zsec
R> st <- start(tmp)
```
R> Epoch <- st - as.numeric(st)
R> time(tmp) <- as.integer(time(tmp) + 1e-7) + Epoch
R> # find index of last value in each one second interval
R> ix <- !duplicated(time(tmp), fromLast = TRUE)
R> # merge with grid
R> merge(tmp[ix], zoo(, seq(start(tmp), end(tmp), "sec")))

2009-02-16 05:00:03 2009-02-16 05:00:04 2009-02-16 05:00:05
  3 NA 10

R> # Here is a function which generalizes the above:
R>
R> intraday.discretise <- function(b, Nsec) {
+ st <- start(b)
+ time(b) <- Nsec * as.integer(time(b)+1e-7) %/% Nsec + st -
+ as.numeric(st)
+ ix <- !duplicated(time(b), fromLast = TRUE)
+ merge(b[ix], zoo(, seq(start(b), end(b), paste(Nsec, "sec")))))
+ }
R> intraday.discretise(zsec, 1)

2009-02-16 05:00:03 2009-02-16 05:00:04 2009-02-16 05:00:05
  3 NA 10

R>

**Query Yahoo! Finance**

When connected to the internet, Yahoo! Finance can be easily queried using the `get.hist.quote` function in

R> library("tseries")

From version 0.9-30 on, `get.hist.quote` by default returns "zoo" series with a "Date" attribute (in previous versions these had to be transformed from "ts" ‘by hand’).

A daily series can be obtained by:

R> sunw <- get.hist.quote(instrument = "SUNW", start = "2004-01-01", end = "2004-12-31")

A monthly series can be obtained and transformed by

R> sunw2 <- get.hist.quote(instrument = "SUNW", start = "2004-01-01", end = "2004-12-31",
+ compression = "m", quote = "Close")

Here, "yearmon" dates might be even more useful:

R> time(sunw2) <- as.yearmon(time(sunw2))
The same series can equivalently be computed from the daily series via

\[
R> \text{sunw3} \leftarrow \text{aggregate(sunw[, } \text{"Close"}, \text{ as.yearmon, tail, 1)}
\]

The corresponding returns can be computed via

\[
R> r \leftarrow \text{prices2returns(sunw3)}
\]

where \(r\) is still a "zoo" series.

**Query Oanda**

Similarly you can obtain historical exchange rates from [http://www.oanda.com/](http://www.oanda.com/) using `get.hist.quote`. A daily series of EUR/USD exchange rates can be queried by

\[
R> \text{eur.usd} \leftarrow \text{get.hist.quote(instrument = } \text{"EUR/USD", provider = } \text{"oanda", start = } \text{"2004-01-}}
\]

This contains the exchange rates for every day in 2004. However, it is common practice in many situations to exclude the observations from weekends. To do so, we write a little convenience function which can determine for a vector of "Date" observations whether it is a weekend or not

\[
R> \text{is.weekend} \leftarrow \text{function(x) (}} (\text{as.numeric(x)-2) \mod 7) < 2\]

Based on this we can omit all observations from weekends

\[
R> \text{eur.usd} \leftarrow \text{eur.usd[!is.weekend(time(eur.usd))]}\]

The function `is.weekend` introduced above exploits the fact that a "Date" is essentially the number of days since 1970-01-01, a Thursday. A more intelligible function which yields identical results could be based on the "POSIXlt" class

\[
R> \text{is.weekend} \leftarrow \text{function(x) }
+ \text{ } (\text{as.POSIXlt(x))}
+ \text{x$wday > 5 | x$wday < 1}
+ \}
\]

**Summaries**

Here we create a daily series and then find the series of quarterly means and standard deviations and also for weekly means and standard deviations where we define weeks to end on Tuesday.

We do the above separately for mean and standard deviation, binding the two results together and then show a different approach in which we define a custom `ag` function that can accept multiple function names as a vector argument.
R> date1 <- seq(as.Date("2001-01-01"), as.Date("2002-12-1"), by = "day")
R> len1 <- length(date1)
R> set.seed(1) # to make it reproducible
R> data1 <- zoo(rnorm(len1), date1)
R> # quarterly summary
R> 
R> data1q.mean <- aggregate(data1, as.yearqtr, mean)
R> data1q.sd <- aggregate(data1, as.yearqtr, sd)
R> head(cbind(mean = data1q.mean, sd = data1q.sd), main = "Quarterly")
