

# Package ‘gap’

January 22, 2023

**Version** 1.5-1

**Date** 2023-1-22

**Title** Genetic Analysis Package

**URL** <https://github.com/jinghuazhao/R>

**BugReports** <https://github.com/jinghuazhao/R/issues>

**Depends** R (>= 2.10), gap.datasets

**Imports** dplyr, ggplot2, plotly

**Suggests** BradleyTerry2, DiagrammeR, DOT, MASS, Matrix, MCMCglmm, R2jags, bdsmatrix, bookdown, calibrate, circlize, coda, cowplot, coxme, foreign, forestplot, genetics, grid, haplo.stats, htmlwidgets, jsonlite, kinship2, knitr, lattice, magic, manhattanly, matrixStats, meta, metafor, nlme, pedigree, pedigreemm, plotrix, readr, reshape, rmarkdown, rmeta, rms, survival

**VignetteBuilder** knitr

**Enhances** shiny

## Description

As first reported [Zhao, J. H. 2007. “gap: Genetic Analysis Package”. J Stat Soft 23(8):1-18. <[doi:10.18637/jss.v023.i08](https://doi.org/10.18637/jss.v023.i08)>], it is designed as an integrated package for genetic data analysis of both population and family data. Currently, it contains functions for sample size calculations of both population-based and family-based designs, probability of familial disease aggregation, kinship calculation, statistics in linkage analysis, and association analysis involving genetic markers including haplotype analysis with or without environmental covariates. Over years, the package has been developed in-between many projects hence also in line with the name (gap).

**License** GPL (>= 2)

**LazyData** Yes

**LazyLoad** Yes

**NeedsCompilation** yes

**Repository** CRAN

**Encoding** UTF-8

a2g *Allele-to-genotype conversion*

**Description**

Allele-to-genotype conversion

**Usage**

a2g(a1, a2)

**Arguments**

a1	first allele.
a2	second allele.

---

ab

*Test/Power calculation for mediating effect*

---

### Description

This function tests for or obtains power of mediating effect based on estimates of two regression coefficients and their standard errors. Note that for binary outcome or mediator, one should use log-odds ratio and its standard error.

### Usage

```
ab(  
  type = "power",  
  n = 25000,  
  a = 0.15,  
  sa = 0.01,  
  b = log(1.19),  
  sb = 0.01,  
  alpha = 0.05,  
  fold = 1  
)
```

### Arguments

type	string option: "test", "power".
n	default sample size to be used for power calculation.
a	regression coefficient from independent variable to mediator.
sa	SE(a).
b	regression coefficient from mediator variable to outcome.
sb	SE(b).
alpha	size of significance test for power calculation.
fold	fold change for power calculation, as appropriate for a range of sample sizes.

### Value

The returned value are z-test and significance level for significant testing or sample size/power for a given fold change of the default sample size.

### Author(s)

Jing Hua Zhao

## End(Not run)
```

---

AE3

*AE model using nuclear family trios*

---

## Description

This function is adapted from example 7.1 of Rabe-Hesketh et al. (2008). It also provides heritability estimate and confidence intervals.

## Usage

```
AE3(model, random, data, seed = 1234, n.sim = 50000, verbose = TRUE)
```

**Arguments**

model	a linear mixed model formula, see example below.
random	random effect, see example below.
data	data to be analyzed.
seed	random number seed.
n.sim	number of simulations.
verbose	a flag for printing out results.

**Value**

The returned value is a list containing:

**lme.result** the linear mixed model result.

**h2** the heritability estimate.

**CL** confidence intervals.

**Note**

Adapted from f.mbf.R from the paper.

**Examples**

```
## Not run:
require(gap.datasets)
AE3(bwt ~ male + first + midage + highage + birthyr,
    list(familyid = pdIdent(~var1 + var2 + var3 -1)), mfblong)

## End(Not run)
```

allele.recode            *Allele recoding*

---

**Description**

Allele recoding

**Usage**

```
allele.recode(a1, a2, miss.val = NA)
```

**Arguments**

a1	first allele.
a2	second allele.
miss.val	missing value.

---

asplot                    *Regional association plot*

---

**Description**

This function obtains regional association plot for a particular locus, based on the information about recombination rates, linkage disequilibria between the SNP of interest and neighbouring ones, and single-point association tests p values.

**Usage**

```
asplot(  
  locus,  
  map,  
  genes,  
  flanking = 1000,  
  best.pval = NULL,  
  sf = c(4, 4),  
  logpmax = 10,  
  pch = 21  
)
```

**Arguments**

locus	Data frame with columns c("CHR", "POS", "NAME", "PVAL", "RSQR") containing association results.
map	Genetic map, i.e. c("POS", "THETA", "DIST").
genes	Gene annotation with columns c("START", "STOP", "STRAND", "GENE").
flanking	Flanking length.
best.pval	Best p value for the locus of interest.
sf	scale factors for p values and recombination rates, smaller values are necessary for gene dense regions.
logpmax	Maximum value for $-\log_{10}(p)$ .
pch	Plotting character for the SNPs to be highlighted, e.g., 21 and 23 refer to circle and diamond.

**Details**

Note that the best p value is not necessarily within locus in the original design.

## End(Not run)

```

---

b2r

---

*Obtain correlation coefficients and their variance-covariances*

---

## Description

This function converts linear regression coefficients of phenotype on single nucleotide polymorphisms (SNPs) into Pearson correlation coefficients with their variance-covariance matrix. It is useful as a preliminary step for meta-analyze SNP-trait associations at a given region. Between-SNP correlations (e.g., from HapMap) are required as auxiliary information.

## Usage

```
b2r(b, s, rho, n)
```

## Arguments

b	the vector of linear regression coefficients.
s	the corresponding vector of standard errors.
rho	triangular array of between-SNP correlation.
n	the sample size.

**Value**

The returned value is a list containing:

**r** the vector of correlation coefficients

**V** the variance-covariance matrix of correlations

---

BFDP

*Bayesian false-discovery probability*

---

**Description**

This function calculates BFDP, the approximate  $P(H_0|\hat{\theta})$ , given an estimate of the log relative risk,  $\hat{\theta}$ , the variance of this estimate,  $V$ , the prior variance,  $W$ , and the prior probability of a non-null association. When `logscale=TRUE`, the function accepts an estimate of the relative risk,  $\hat{RR}$ , and the upper point of a 95% confidence interval  $RR_{hi}$ .

**Usage**

```
BFDP(a, b, pi1, W, logscale = FALSE)
```

**Arguments**

a	parameter value at which the power is to be evaluated.
b	the variance for a, or the upper point ( $RR_{hi}$ ) of a 95%CI if logscale=FALSE.
pi1	the prior probability of a non-null association.
W	the prior variance.
logscale	FALSE=the original scale, TRUE=the log scale.

**Value**

The returned value is a list with the following components:

**PH0** probability given a,b)

**PH1** probability given a,b,W)

**BF** Bayes factor,  $P_{H_0}/P_{H_1}$

**BFDP** Bayesian false-discovery probability

**ABF** approximate Bayes factor

**ABFDP** approximate Bayesian false-discovery probability

bt

*Bradley-Terry model for contingency table*

---

### Description

This function calculates statistics under Bradley-Terry model.

**Usage**

```
bt(x)
```

**Arguments**

x                    the data table.

**Value**

The returned value is a list containing:

**y** A column of 1

**count** the frequency count/weight

**allele** the design matrix

**bt.glm** a glm.fit object

**etdt.dat** a data table that can be used by ETDT

**Note**

Adapted from a SAS macro for data in the example section.

ccsize

*Power and sample size for case-cohort design***Description**

The power of the test is according to

$$\Phi \left( Z_{\alpha} + m^{1/2} \theta \sqrt{\frac{p_1 p_2 p_D}{q + (1 - q) p_D}} \right)$$

where  $\alpha$  is the significance level,  $\theta$  is the log-hazard ratio for two groups,  $p_j$ ,  $j=1, 2$ , are the proportion of the two groups in the population.  $m$  is the total number of subjects in the subcohort,  $p_D$  is the proportion of the failures in the full cohort, and  $q$  is the sampling fraction of the subcohort.

**Usage**

```
ccsize(n, q, pD, p1, theta, alpha, beta = 0.2, power = FALSE, verbose = FALSE)
```

**Arguments**

n	the total number of subjects in the cohort.
q	the sampling fraction of the subcohort.
pD	the proportion of the failures in the full cohort.
p1	proportions of the two groups (p2=1-p1).
theta	log-hazard ratio for two groups.
alpha	type I error – significant level.
beta	type II error.
power	if specified, the power for which sample size is calculated.
verbose	error messages are explicitly printed out.

**Details**

Alternatively, the sample size required for the subcohort is

$$m = nBp_D / (n - B(1 - p_D))$$

where  $B = (Z_{1-\alpha} + Z_\beta)^2 / (\theta^2 p_1 p_2 p_D)$ , and  $n$  is the size of cohort.

When infeasible configurations are specified, a sample size of -999 is returned.

**Value**

The returned value is a value indicating the power or required sample size.

**Note**

Programmed for EPIC study. keywords misc

chow.test

*Chow's test for heterogeneity in two regressions*

---

### Description

Chow's test is for differences between two or more regressions. Assuming that errors in regressions 1 and 2 are normally distributed with zero mean and homoscedastic variance, and they are independent of each other, the test of regressions from sample sizes  $n_1$  and  $n_2$  is then carried out using the following steps. 1. Run a regression on the combined sample with size  $n = n_1 + n_2$  and obtain within group sum of squares called  $S_1$ . The number of degrees of freedom is  $n_1 + n_2 - k$ , with  $k$  being the number of parameters estimated, including the intercept. 2. Run two regressions on the two individual samples with sizes  $n_1$  and  $n_2$ , and obtain their within group sums of square  $S_2 + S_3$ , with  $n_1 + n_2 - 2k$  degrees of freedom. 3. Conduct an  $F_{(k,n_1+n_2-2k)}$  test defined by

$$F = \frac{[S_1 - (S_2 + S_3)]/k}{[(S_2 + S_3)/(n_1 + n_2 - 2k)]}$$

If the  $F$  statistic exceeds the critical  $F$ , we reject the null hypothesis that the two regressions are equal.

### Usage

```
chow.test(y1, x1, y2, x2, x = NULL)
```

### Arguments

<code>y1</code>	a vector of dependent variable.
<code>x1</code>	a matrix of independent variables.
<code>y2</code>	a vector of dependent variable.
<code>x2</code>	a matrix of independent variables.
<code>x</code>	a known matrix of independent variables.

### Details

In the case of haplotype trend regression, haplotype frequencies from combined data are known, so can be directly used.

### Value

The returned value is a vector containing (please use subscript to access them):

**F** the F statistic  
**df1** the numerator degree(s) of freedom  
**df2** the denominator degree(s) of freedom  
**p** the p value for the F test

### Note

adapted from chow.R.

chr\_pos\_a1\_a2

*SNP id by chr:pos+a1/a2*

---

## Description

This function generates unique identifiers for variants

## Usage

```
chr_pos_a1_a2(
  chr,
  pos,
  a1,
```

```

a2,
prefix = "chr",
seps = c(":", "_", "-"),
uppercase = TRUE
)

```

### Arguments

chr	Chromosome.
pos	Position.
a1	Allele 1.
a2	Allele 2.
prefix	Prefix of the identifier.
seps	Delimiters.
uppercase	A flag to return in upper case.

### Value

Identifier.

### Examples

```

# rs12075
chr_pos_a1_a2(1,159175354,"A","G",prefix="chr",seps=c(":", "_", "-"),uppercase=TRUE)

```

---

circos.cis.vs.trans.plot

*circos plot of cis/trans classification*

---

### Description

The function implements a circos plot at the early stage of SCALLOP-INF meta-analysis.

### Usage

```
circos.cis.vs.trans.plot(hits, panel, id, radius = 1e+06)
```

### Arguments

hits	A text file as input data with variables named "CHR", "BP", "SNP", "prot".
panel	Protein panel with prot(ein), uniprot (id) and "chr", "start", "end", "gene".
id	Identifier.
radius	The flanking distance as cis.

**Value**

None.

**Examples**

```
## Not run:  
  circos.cis.vs.trans.plot(hits="INF1.clumped", panel=inf1, id="uniprot")  
  
## End(Not run)
```

---

circos.cnvplot      *circos plot of CNVs.*

---

**Description**

The function plots frequency of CNVs.

**Usage**

```
circos.cnvplot(data)
```

**Arguments**

data                  CNV data containing chromosome, start, end and freq.

**Value**

None.

**Examples**

```
## Not run:  
  circos.cnvplot(cnv)  
  
## End(Not run)
```

---

circos.mhtplot	<i>circos Manhattan plot with gene annotation</i>
----------------	---

---

**Description**

The function generates circos Manhattan plot with gene annotation.

**Usage**

```
circos.mhtplot(data, glist)
```

**Arguments**

data	Data to be used.
glist	A gene list.

**Value**

None.

**Examples**

```
## Not run:  
require(gap.datasets)  
glist <- c("IRS1", "SPRY2", "FTO", "GRIK3", "SNED1", "HTR1A", "MARCH3", "WISP3",  
          "PPP1R3B", "RP1L1", "FDFT1", "SLC39A14", "GFRA1", "MC4R")  
circos.mhtplot(mhtdata, glist)  
  
## End(Not run)
```

---

circos.mhtplot2	<i>Another circos Manhattan plot</i>
-----------------	--------------------------------------

---

**Description**

This is adapted from work for a recent publication. It enables a y-axis to the  $-\log_{10}(P)$  for association statistics

**Usage**

```
circos.mhtplot2(dat, labs, species = "hg18", ticks = 0:3 * 10, y = 20)
```

**Arguments**

<code>dat</code>	Data to be plotted with variables <code>chr</code> , <code>pos</code> , <code>log10p</code> .
<code>labs</code>	Data on labels.
<code>species</code>	Genome build.
<code>ticks</code>	Tick positions.
<code>y</code>	Starting position of y-axis label.

**Value**

There is no return value but a plot.

**Examples**

```
## Not run:
require(gap.datasets)
library(dplyr)
glist <- c("IRS1", "SPRY2", "FTO", "GRIK3", "SNED1", "HTR1A", "MARCH3", "WISP3",

# https://www.rapidtables.com/web/color/RGB_Color.html

## End(Not run)
```

---

cis.vs.trans.classification

*A cis/trans classifier*

---

**Description**

The function classifies variants into cis/trans category according to a panel which contains `id`, `chr`, `start`, `end`, `gene` variables.

**Usage**

```
cis.vs.trans.classification(hits, panel, id, radius = 1e+06)
```

**Arguments**

hits	Data to be used, which contains prot, Chr, bp, id and/or other information such as SNPid.
panel	Panel data.
id	Identifier.
radius	The flanking distance for variants.

**Value**

The cis/trans classification.

**Author(s)**

James Peters

**Examples**

```

cis.vs.trans.classification(hits=jma.cojo, panel=inf1, id="uniprot")
## Not run:
INF <- Sys.getenv("INF")
f <- file.path(INF, "work", "INF1.merge")
clumped <- read.delim(f, as.is=TRUE)
hits <- merge(clumped[c("CHR", "POS", "MarkerName", "prot", "log10p")],
             inf1[c("prot", "uniprot")], by="prot")
names(hits) <- c("prot", "Chr", "bp", "SNP", "log10p", "uniprot")
cistrans <- cis.vs.trans.classification(hits, inf1, "uniprot")
cis.vs.trans <- with(cistrans, data)
knitr::kable(with(cistrans, table), caption="Table 1. cis/trans classification")
with(cistrans, total)

## End(Not run)

```

---

cnvplot

*genomewide plot of CNVs*

---

**Description**

The function generates a plot containing genomewide copy number variants (CNV) chr, start, end, freq(uencies).

**Usage**

```
cnvplot(data)
```

**Arguments**

data	Data to be used.
------	------------------

**Value**

None.

**Examples**

```
knitr::kable(cnv,caption="A CNV dataset")
cnvplot(cnv)
```

---

comp.score

*score statistics for testing genetic linkage of quantitative trait*

---

**Description**

The function empirically estimate the variance of the score functions. The variance-covariance matrix consists of two parts: the additive part and the part for the individual-specific environmental effect. Other reasonable decompositions are possible.

**Usage**

```
comp.score(
  ibddata = "ibd_dist.out",
  phenotype = "pheno.dat",
  mean = 0,
  var = 1,
  h2 = 0.3
)
```

**Arguments**

ibddata	The output file from GENEHUNTER using command "dump ibd". The default file name is <i>ibd_dist.out</i> .
phenotype	The file of pedigree structure and trait value. The default file name is "pheno.dat". Columns (no headings) are: family ID, person ID, father ID, mother ID, gender, trait value, where Family ID and person ID must be numbers, not characters. Use character "NA" for missing phenotypes.
mean	(population) mean of the trait, with a default value of 0.
var	(population) variance of the trait, with a default value of 1.
h2	heritability of the trait, with a default value of 0.3.

**Details**

This program has the following improvement over "score.r":

1. It works with selected nuclear families
2. Trait data on parents (one parent or two parents), if available, are utilized.

3. Besides a statistic assuming no locus-specific dominance effect, it also computes a statistic that allows for such effect. It computes two statistics instead of one.

Function "merge" is used to merge the IBD data for a pair with the transformed trait data (i.e.,  $w_k w_l$ ).

### Value

a matrix with each row containing the location and the statistics and their p-values.

### Note

Adapt from score2.r.

### Examples

```
## Not run:
# An example based on GENEHUNTER version 2.1, with quantitative trait data in file
# "pheno.dat" generated from the standard normal distribution. The following
# example shows that it is possible to automatically call GENEHUNTER using R
# function "system".

cwd <- getwd()
cs.dir <- file.path(find.package("gap"),"tests/comp.score")
setwd(cs.dir)
dir()
# system("gh < gh.inp")
cs.default <- comp.score()
setwd(cwd)

## End(Not run)
```

---

cs	<i>Credible set</i>
----	---------------------

---

**Description**

The function implements credible set as in fine-mapping.

**Usage**

```
cs(tbl, b = "Effect", se = "StdErr", log_p = NULL, cutoff = 0.95)
```

**Arguments**

tbl	Input data.
b	Effect size.
se	Standard error.
log_p	if not NULL it will be used to derive z-statistic
cutoff	Threshold for inclusion.

**Value**

Credible set.

**Examples**

```
## Not run:
\preformatted{
  zcat METAL/4E.BP1-1.tbl.gz | \
  awk 'NR==1 || ($1==4 && $2 >= 187158034 - 1e6 && $2 < 187158034 + 1e6)' > 4E.BP1.z
}
tbl <- within(read.delim("4E.BP1.z"),{logp <- logp(Effect/StdErr)})
z <- cs(tbl)
l <- cs(tbl,log_p="logp")

## End(Not run)
```

---

ESplot	<i>Effect-size plot</i>
--------	-------------------------

---

**Description**

The function accepts parameter estimates and their standard errors for a range of models.

**Usage**

```
ESplot(ESdat, alpha = 0.05, fontsize = 12)
```

**Arguments**

ESdat	A data frame consisting of model id, parameter estimates and standard errors.
alpha	Type-I error rate used to construct 100(1-alpha) confidence interval.
fontsize	size of font.

**Value**

A high resolution plot object.

**Author(s)**

Jing Hua Zhao

**Examples**

```
rs12075 <- data.frame(id=c("CCL2", "CCL7", "CCL8", "CCL11", "CCL13", "CXCL6", "Monocytes"),
                     b=c(0.1694, -0.0899, -0.0973, 0.0749, 0.189, 0.0816, 0.0338387),
                     se=c(0.0113, 0.013, 0.0116, 0.0114, 0.0114, 0.0115, 0.00713386))
ESplot(rs12075)

# The function replaces an older implementation.
within(data.frame(
  id=c("Basic model", "Adjusted", "Moderately adjusted", "Heavily adjusted", "Other"),
  b=log(c(4.5, 3.5, 2.5, 1.5, 1)),
  se=c(0.2, 0.1, 0.2, 0.3, 0.2)
), {
  lc1 <- exp(b-1.96*se)
  uc1 <- exp(b+1.96*se)
  x <- seq(-2, 8, length=length(id))
  y <- 1:length(id)
  plot(x, y, type="n", xlab="", ylab="", axes=FALSE)
  points((lc1+uc1)/2, y, pch=22, bg="black", cex=3)
  segments(lc1, y, uc1, y, lwd=3, lty="solid")
  axis(1, cex.axis=1.5, lwd=0.5)
  par(las=1)
  abline(v=1)
  axis(2, labels=id, at=y, lty="blank", hadj=0.2, cex.axis=1.5)
  title("A fictitious plot")
})
```

---

fbsize

*Sample size for family-based linkage and association design*

---

**Description**

This function implements Risch and Merikangas (1996) statistics evaluating power for family-based linkage (affected sib pairs, ASP) and association design. They are potentially useful in the prospect of genome-wide association studies.

**Usage**

```
fbsize(  
  gamma,  
  p,  
  alpha = c(1e-04, 1e-08, 1e-08),  
  beta = 0.2,  
  debug = 0,  
  error = 0  
)
```

**Arguments**

gamma	genotype relative risk assuming multiplicative model.
p	frequency of disease allele.
alpha	Type I error rates for ASP linkage, TDT and ASP-TDT.
beta	Type II error rate.
debug	verbose output.
error	0=use the correct formula,1=the original paper.

**Details**

The function calls auxiliary functions `sn()` and `strlen`; `sn()` contains the necessary thresholds for power calculation while `strlen()` evaluates length of a string (generic).

**Value**

The returned value is a list containing:

**gamma** input gamma.  
**p** input p.  
**n1** sample size for ASP.  
**n2** sample size for TDT.  
**n3** sample size for ASP-TDT.  
**lambdao** lambda o.  
**lambdas** lambda s.

**Note**

extracted from `rm.c`.

```

FPRP

*False-positive report probability***Description**

The function calculates the false positive report probability (FPRP), the probability of no true association between a genetic variant and disease given a statistically significant finding, which depends not only on the observed P value but also on both the prior probability that the association is real and the statistical power of the test. An associate result is the false negative reported probability (FNRP). See example for the recommended steps.

**Usage**

```
FPRP(a, b, pi0, ORlist, logscale = FALSE)
```

**Arguments**

a parameter value at which the power is to be evaluated.  
 b the variance for a, or the upper point of a 95%CI if logscale=FALSE.  
 pi0 the prior probability that  $H_0$  is true.  
 ORlist a vector of ORs that is most likely.  
 logscale FALSE=a,b in original scale, TRUE=a, b in log scale.

**Details**

The FPRP and FNRP are derived as follows. Let  $H_0$ =null hypothesis (no association),  $H_A$ =alternative hypothesis (association). Since classic frequentist theory considers they are fixed, one has to resort to Bayesian framework by introducing prior,  $\pi = P(H_0 = TRUE) = P(\text{association})$ . Let  $T$ =test statistic, and  $P(T > z_\alpha | H_0 = TRUE) = P(\text{rejecting } H_0 | H_0 = TRUE) = \alpha$ ,  $P(T > z_\alpha | H_0 = FALSE) = P(\text{rejecting } H_0 | H_A = TRUE) = 1 - \beta$ . The joint probability of test and truth of hypothesis can be expressed by  $\alpha$ ,  $\beta$  and  $\pi$ .

Truth of $H_A$	significant	nonsignificant	Total
TRUE	$(1 - \beta)\pi$	$\beta\pi$	$\pi$
FALSE	$\alpha(1 - \pi)$	$(1 - \alpha)(1 - \pi)$	$1 - \pi$
Total	$(1 - \beta)\pi + \alpha(1 - \pi)$	$\beta\pi + (1 - \alpha)(1 - \pi)$	1

We have  $FPRP = P(H_0 = TRUE | T > z_\alpha) = \alpha(1 - \pi) / [\alpha(1 - \pi) + (1 - \beta)\pi] = \{1 + \pi / (1 - \pi)\} [(1 - \beta) / \alpha]^{-1}$  and similarly  $FNRP = \{1 + [(1 - \alpha) / \beta] [(1 - \pi) / \pi]\}^{-1}$ .

**Value**

The returned value is a list with components,

**p** p value corresponding to a,b  
**power** the power corresponding to the vector of ORs  
**FPRP** False-positive report probability  
**FNRP** False-negative report probability

---

g2a

*Conversion of a genotype identifier to alleles*

---

### Description

Conversion of a genotype identifier to alleles

### Usage

```
g2a(g)
```

### Arguments

g                    a genotype identifier.

---

gc.em

*Gene counting for haplotype analysis*

---

### Description

Gene counting for haplotype analysis with missing data, adapted for hap.score

### Usage

```

gc.em(
  data,
  locus.label = NA,
  converge.eps = 1e-06,
  maxiter = 500,
  handle.miss = 0,
  miss.val = 0,
  control = gc.control()
)

```

**Arguments**

<code>data</code>	Matrix of alleles, such that each locus has a pair of adjacent columns of alleles, and the order of columns corresponds to the order of loci on a chromosome. If there are K loci, then $\text{ncol}(\text{data}) = 2 * K$ . Rows represent alleles for each subject.
<code>locus.label</code>	Vector of labels for loci, of length K (see definition of data matrix).
<code>converge.eps</code>	Convergence criterion, based on absolute change in log likelihood (lnlike).
<code>maxiter</code>	Maximum number of iterations of EM.
<code>handle.miss</code>	a flag for handling missing genotype data, 0=no, 1=yes.
<code>miss.val</code>	missing value.
<code>control</code>	a function, see <a href="#">genecounting</a> .

**Value**

List with components:

**converge** Indicator of convergence of the EM algorithm (1=converged, 0 = failed).

**niter** Number of iterations completed in the EM algorithm.

**locus.info** A list with a component for each locus. Each component is also a list, and the items of a locus-specific list are the locus name and a vector for the unique alleles for the locus.

**locus.label** Vector of labels for loci, of length K (see definition of input values).

**haplotype** Matrix of unique haplotypes. Each row represents a unique haplotype, and the number of columns is the number of loci.

**hap.prob** Vector of mle's of haplotype probabilities. The *i*th element of hap.prob corresponds to the *i*th row of haplotype.

**hap.prob.noLD** Similar to hap.prob, but assuming no linkage disequilibrium.

**lnlike** Value of lnlike at last EM iteration (maximum lnlike if converged).

**lr** Likelihood ratio statistic to test no linkage disequilibrium among all loci.

**indx.subj** Vector for index of subjects, after expanding to all possible pairs of haplotypes for each person. If  $\text{indx} = i$ , then *i* is the *i*th row of input matrix data. If the *i*th subject has *n* possible pairs of haplotypes that correspond to their marker phenotype, then *i* is repeated *n* times.

**nreps** Vector for the count of haplotype pairs that map to each subject's marker genotypes.

**hap1code** Vector of codes for each subject's first haplotype. The values in hap1code are the row numbers of the unique haplotypes in the returned matrix haplotype.

**hap2code** Similar to hap1code, but for each subject's second haplotype.

**post** Vector of posterior probabilities of pairs of haplotypes for a person, given their marker phenotypes.

**htrtable** A table which can be used in haplotype trend regression

**Note**

Adapted from GENECOUNTING.

---

gc.lambda

*Estimation of the genomic control inflation statistic (lambda)*

---

**Description**

Estimation of the genomic control inflation statistic (lambda)

**Usage**

```
gc.lambda(p)
```

**Arguments**

p                    A vector of p values.

**Value**

Estimate of inflation factor.

**Examples**

```
set.seed(12345)  
p <- runif(100)  
lambda <- gc.lambda(p)
```

---

gcontrol                      *genomic control*

---

### Description

The Bayesian genomic control statistics with the following parameters,

### Usage

```
gcontrol(
  data,
  zeta = 1000,
  kappa = 4,
  tau2 = 1,
  epsilon = 0.01,
  ngib = 500,
  burn = 50,
  idum = 2348
)
```

### Arguments

data	the data matrix.
zeta	program constant with default value 1000.
kappa	multiplier in prior for mean with default value 4.
tau2	multiplier in prior for variance with default value 1.
epsilon	prior probability of marker association with default value 0.01.
ngib	number of Gibbs steps, with default value 500.
burn	number of burn-ins with default value 50.
idum	seed for pseudorandom number sequence.

### Details

n	number of loci under consideration
lambdahat	median(of the n trend statistics)/0.46 Prior for noncentrality parameter $A_i$ is Normal( $\sqrt{\text{lambdahat}}\text{kappa}$ , $\text{lambdahat}*\text{tau2}$ )
kappa	multiplier in prior above, set at $1.6 * \sqrt{\log(n)}$
tau2	multiplier in prior above
epsilon	prior probability a marker is associated, set at $10/n$
ngib	number of cycles for the Gibbs sampler after burn in
burn	number of cycles for the Gibbs sampler to burn in

Armitage's trend test along with the posterior probability that each marker is associated with the disorder is given. The latter is not a p-value but any value greater than 0.5 (pout) suggests association.

### Value

The returned value is a list containing:

**deltot** the probability of being an outlier

**x2** the  $\chi^2$  statistic

**A** the A vector

### Note

Adapted from gcontrol by Bobby Jones and Kathryn Roeder, use -Dexecutable for standalone program, function getnum in the original code needs %\*s to skip id string

        1,2,3,4,5,61, 1,2,11,23,1,2, 10,11,2,12,1,11)
test<-matrix(test,nrow=6,byrow=T)
gcontrol(test)

## End(Not run)
```

---

gcontrol2

*genomic control based on p values*

---

### Description

The function obtains 1-df  $\chi^2$  statistics (observed) according to a vector of p values, and the inflation factor (lambda) according to medians of the observed and expected statistics. The latter is based on the empirical distribution function (EDF) of 1-df  $\chi^2$  statistics.

**Usage**

```
gcontrol2(p, col = palette()[4], lcol = palette()[2], ...)
```

**Arguments**

<code>p</code>	a vector of observed p values.
<code>col</code>	colour for points in the Q-Q plot.
<code>lcol</code>	colour for the diagonal line in the Q-Q plot.
<code>...</code>	other options for plot.

**Details**

It would be appropriate for genetic association analysis as of 1-df Armitage trend test for case-control data; for 1-df additive model with continuous outcome one has to consider the compatibility with p values based on z-/t- statistics.

**Value**

A list containing:

**x** the expected  $\chi^2$  statistics

**y** the observed  $\chi^2$  statistics

**lambda** the inflation factor

**Author(s)**

Jing Hua Zhao

**References**

Devlin B, Roeder K (1999) Genomic control for association studies. *Biometrics* 55:997-1004

**Examples**

```
## Not run:  
x2 <- rchisq(100,1,.1)  
p <- pchisq(x2,1,lower.tail=FALSE)  
r <- gcontrol2(p)  
print(r$lambda)  
  
## End(Not run)
```

gcp

*Permutation tests using GENECOUNTING***Description**

This function is a R port of the GENECOUNTING/PERMUTE program which generates EHPLUS-type statistics including z-tests for individual haplotypes

**Usage**

```
gcp(
  y,
  cc,
  g,
  handle.miss = 1,
  miss.val = 0,
  n.sim = 0,
  locus.label = NULL,
  quietly = FALSE
)
```

**Arguments**

<code>y</code>	A column of 0/1 indicating cases and controls.
<code>cc</code>	analysis indicator, 0 = marker-marker, 1 = case-control.
<code>g</code>	the multilocus genotype data.
<code>handle.miss</code>	a flag with value 1 indicating missing data are allowed.
<code>miss.val</code>	missing value.
<code>n.sim</code>	the number of permutations.
<code>locus.label</code>	label of each locus.
<code>quietly</code>	a flag if TRUE will suppress the screen output.

**Value**

The returned value is a list containing (p.sim and ph when n.sim > 0):

**x2obs** the observed chi-squared statistic  
**pobs** the associated p value  
**zobs** the observed z value for individual haplotypes  
**p.sim** simulated p value for the global chi-squared statistic  
**ph** simulated p values for individual haplotypes

**Note**

Built on gcp.c.

genecounting

*Gene counting for haplotype analysis*

---

**Description**

Gene counting for haplotype analysis with missing data

**Usage**

```
genecounting(data, weight = NULL, loci = NULL, control = gc.control())
```

**Arguments**

<b>data</b>	genotype table.
<b>weight</b>	a column of frequency weights.
<b>loci</b>	an array containing number of alleles at each locus.
<b>control</b>	is a function with the following arguments: <ol style="list-style-type: none"> <li>1. <b>xdata</b>. a flag indicating if the data involves X chromosome, if so, the first column of data indicates sex of each subject: 1=male, 2=female. The marker data are no different from the autosomal version for females, but for males, two copies of the single allele present at a given locus.</li> <li>2. <b>convll</b>. set convergence criteria according to log-likelihood, if its value set to 1</li> <li>3. <b>handle.miss</b>. to handle missing data, if its value set to 1</li> <li>4. <b>eps</b>. the actual convergence criteria, with default value 1e-5</li> <li>5. <b>tol</b>. tolerance for genotype probabilities with default value 1e-8</li> <li>6. <b>maxit</b>. maximum number of iterations, with default value 50</li> <li>7. <b>pl</b>. criteria for trimming haplotypes according to posterior probabilities</li> <li>8. <b>assignment</b>. filename containing haplotype assignment</li> <li>9. <b>verbose</b>. If TRUE, yields print out from the C routine</li> </ol>

**Value**

The returned value is a list containing:

<b>h</b>	haplotype frequency estimates under linkage disequilibrium (LD)
<b>h0</b>	haplotype frequency estimates under linkage equilibrium (no LD)
<b>prob</b>	genotype probability estimates
<b>l0</b>	log-likelihood under linkage equilibrium
<b>l1</b>	log-likelihood under linkage disequilibrium
<b>hapid</b>	unique haplotype identifier (defunct, see gc.em)
<b>npusr</b>	number of parameters according user-given alleles
<b>npdat</b>	number of parameters according to observed
<b>htrtable</b>	design matrix for haplotype trend regression (defunct, see gc.em)
<b>iter</b>	number of iterations used in gene counting
<b>converge</b>	a flag indicating convergence status of gene counting
<b>di0</b>	haplotype diversity under no LD, defined as $1 - \sum(h_0^2)$
<b>di1</b>	haplotype diversity under LD, defined as $1 - \sum(h^2)$
<b>resid</b>	residuals in terms of frequency weights = o - e

gif

*Kinship coefficient and genetic index of familiarity***Description**

The genetic index of familiarity is defined as the mean kinship between all pairs of individuals in a set multiplied by 100,000. Formally, it is defined as

$$100,000 \times \frac{2}{n(n-1)} \sum_{i=1}^{n-1} \sum_{j=i+1}^n k_{ij}$$

where  $n$  is the number of individuals in the set and  $k_{ij}$  is the kinship coefficient between individuals  $i$  and  $j$ .

**Usage**

```
gif(data, gifset)
```

**Arguments**

data	the trio data of a pedigree.
gifset	a subgroup of pedigree members.

**Details**

The scaling is purely for convenience of presentation.

**Value**

The returned value is a list containing:

**gifval** the genetic index of familiarity.

**Note**

Adapted from gif.c, testable with -Dexecutable as standalone program, which can be use for any pair of individuals

**Author(s)**

grid2d	<i>Two-dimensional grid</i>
--------	-----------------------------

---

**Description**

This function build 2-d grids

**Usage**

```
grid2d(  
  chrLen,  
  plot = TRUE,  
  cex.labels = 0.6,  
  xlab = "QTL position",  
  ylab = "Gene position"  
)
```

**Arguments**

chrLen	Lengths of chromosomes; e.g., hg18, hg19 or hg38.
plot	A flag for plot.
cex.labels	A scaling factor for labels.
xlab	X-axis title.
ylab	Y-axis title.

**Value**

A list with two variables.

**n** Number of chromosomes.

**CM** Cumulative lengths starting from 0.

---

h2.jags	<i>Heritability estimation based on genomic relationship matrix using JAGS</i>
---------	--

---

**Description**

Heritability estimation based on genomic relationship matrix using JAGS.

**Usage**

```
h2.jags(
  y,
  x,
  G,
  eps = 1e-04,
  sigma.p = 0,
  sigma.r = 1,
  parms = c("b", "p", "r", "h2"),
  ...
)
```

**Arguments**

y	outcome vector.
x	covariate matrix.
G	genomic relationship matrix.
eps	a positive diagonal perturbation to G.
sigma.p	initial parameter values.
sigma.r	initial parameter values.
parms	monitored parameters.
...	parameters passed to jags, e.g., n.chains, n.burnin, n.iter.

**Details**

This function performs Bayesian heritability estimation using genomic relationship matrix.

**Value**

The returned value is a fitted model from jags().

ex <- h2.jags(y,x,G,sigma.p=0.03,sigma.r=0.014)
print(ex)

## End(Not run)
```

---

h2G

*Heritability and its variance*

---

### **Description**

Heritability and its variance

### **Usage**

```
h2G(V, VCOV, verbose = TRUE)
```

### **Arguments**

V	Variance estimates.
VCOV	Variance-covariance matrix.
verbose	Detailed output.

### **Value**

A list of phenotypic variance/heritability estimates and their variances.

---

h2GE *Heritability and its variance when there is an environment component*

---

**Description**

Heritability and its variance when there is an environment component

**Usage**

h2GE(V, VCOV, verbose = TRUE)

**Arguments**

V	Variance estimates.
VCOV	Variance-covariance matrix.
verbose	Detailed output.

**Value**

A list of phenotypic variance/heritability/GxE interaction estimates and their variances.

---

h2l *Heritability under the liability threshold model*

---

**Description**

Heritability under the liability threshold model

**Usage**

h2l(K = 0.05, P = 0.5, h2, se, verbose = TRUE)

**Arguments**

K	Disease prevalence.
P	Phenotypic variance.
h2	Heritability estimate.
se	Standard error.
verbose	Detailed output.

**Value**

A list of the input heritability estimate/standard error and their counterpart under liability threshold model, the normal deviate..

---

h2\_mzdz

*Heritability estimation according to twin correlations*

---

**Description**

Heritability and variance estimation according to twin pair correlations.

**Usage**

```
h2_mzdz(
  mzDat = NULL,
  dzDat = NULL,
  rmz = NULL,
  rdz = NULL,
  nmz = NULL,
  ndz = NULL,
  selV = NULL
)
```

**Arguments**

mzDat	a data frame for monozygotic twins (MZ).
dzDat	a data frame for dizygotic twins (DZ).
rmz	correlation for MZ twins.
rdz	correlation for DZ twins.
nmz	sample size for MZ twins.
ndz	sample size for DZ twins.
selV	names of variables for twin and cotwin.

**Details**

The example section shows how to obtain bootstrap 95%CI.

**Value**

The returned value is a matrix containing heritability and their variance estimations for "h2", "c2", "e2", "vh", "vc", "ve".

hap *Haplotype reconstruction*

---

**Description**

Haplotype reconstruction using sorting and trimming algorithms.

**Usage**

```
hap(  
  id,  
  data,  
  nloci,  
  loci = rep(2, nloci),  
  names = paste("loci", 1:nloci, sep = ""),  
  control = hap.control()  
)
```

**Arguments**

id	a column of subject id.
data	genotype table.
nloci	number of loci.
loci	number of alleles at all loci.
names	locus names.
control	is a call to hap.control().

**Details**

The package can handle much larger number of multiallelic loci. For large sample size with relatively small number of multiallelic loci, genecounting should be used.

**Value**

The returned value is a list containing:

**ll** log-likelihood assuming linkage disequilibrium  
**converge** convergence status, 0=failed, 1=succeeded  
**niter** number of iterations

**Note**

adapted from hap.

hap.control

*Control for haplotype reconstruction*

---

## Description

Control for haplotype reconstruction

## Usage

```
hap.control(
  mb = 0,
  pr = 0,
  po = 0.001,
  to = 0.001,
  th = 1,
  maxit = 100,
  n = 0,
  ss = 0,
  rs = 0,
```

```

rp = 0,
ro = 0,
rv = 0,
sd = 0,
mm = 0,
mi = 0,
mc = 50,
ds = 0.1,
de = 0,
q = 0,
hapfile = "hap.out",
assignfile = "assign.out"
)

```

### Arguments

mb	Maximum dynamic storage to be allocated, in Mb.
pr	Prior (ie population) probability threshold.
po	Posterior probability threshold.
to	Log-likelihood convergence tolerance.
th	Posterior probability threshold for output.
maxit	Maximum EM iteration.
n	Force numeric allele coding (1/2) on output (off).
ss	Tab-delimited spreadsheet file output (off).
rs	Random starting points for each EM iteration (off).
rp	Restart from random prior probabilities.
ro	Loci added in random order (off).
rv	Loci added in reverse order (off).
sd	Set seed for random number generator (use date+time).
mm	Repeat final maximization multiple times.
mi	Create multiple imputed datasets. If set >0.
mc	Number of MCMC steps between samples.
ds	Starting value of Dirichlet prior parameter.
de	Finishing value of Dirichlet prior parameter.
q	Quiet operation (off).
hapfile	a file for haplotype frequencies.
assignfile	a file for haplotype assignment.

### Value

a list containing the parameter specifications to the function.

hap.em

*Gene counting for haplotype analysis***Description**

Gene counting for haplotype analysis with missing data, adapted for hap.score.

**Usage**

```
hap.em(
  id,
  data,
  locus.label = NA,
  converge.eps = 1e-06,
  maxiter = 500,
  miss.val = 0
)
```

**Arguments**

<code>id</code>	a vector of individual IDs.
<code>data</code>	Matrix of alleles, such that each locus has a pair of adjacent columns of alleles, and the order of columns corresponds to the order of loci on a chromosome. If there are K loci, then <code>ncol(data) = 2*K</code> . Rows represent alleles for each subject.
<code>locus.label</code>	Vector of labels for loci, of length K (see definition of data matrix).
<code>converge.eps</code>	Convergence criterion, based on absolute change in log likelihood (lnlike).
<code>maxiter</code>	Maximum number of iterations of EM.
<code>miss.val</code>	missing value.

**Value**

List with components:

**converge** Indicator of convergence of the EM algorithm (1=converged, 0 = failed).

**niter** Number of iterations completed in the EM algorithm.

**locus.info** A list with a component for each locus. Each component is also a list, and the items of a locus-specific list are the locus name and a vector for the unique alleles for the locus.

**locus.label** Vector of labels for loci, of length K (see definition of input values).

**haplotype** Matrix of unique haplotypes. Each row represents a unique haplotype, and the number of columns is the number of loci.

**hap.prob** Vector of mle's of haplotype probabilities. The *i*th element of `hap.prob` corresponds to the *i*th row of haplotype.

**lnlike** Value of lnlike at last EM iteration (maximum lnlike if converged).

**indx.subj** Vector for index of subjects, after expanding to all possible pairs of haplotypes for each person. If  $\text{indx}=i$ , then  $i$  is the  $i$ th row of input matrix data. If the  $i$ th subject has  $n$  possible pairs of haplotypes that correspond to their marker phenotype, then  $i$  is repeated  $n$  times.

**nreps** Vector for the count of haplotype pairs that map to each subject's marker genotypes.

**hap1code** Vector of codes for each subject's first haplotype. The values in `hap1code` are the row numbers of the unique haplotypes in the returned matrix haplotype.

**hap2code** Similar to `hap1code`, but for each subject's second haplotype.

**post** Vector of posterior probabilities of pairs of haplotypes for a person, given their marker phenotypes.

### Note

Adapted from HAP.

hap.em(id=1:length(h1a[,1]),data=h1a[,3:8],locus.label=c("DQR","DQA","DQB"))

## End(Not run)
```

---

hap.score

*Score statistics for association of traits with haplotypes*

---

### Description

Compute score statistics to evaluate the association of a trait with haplotypes, when linkage phase is unknown and diploid marker phenotypes are observed among unrelated subjects. For now, only autosomal loci are considered. This package `haplo.score` which this function is based is greatly acknowledged.

**Usage**

```
hap.score(
  y,
  geno,
  trait.type = "gaussian",
  offset = NA,
  x.adj = NA,
  skip.haplo = 0.005,
  locus.label = NA,
  miss.val = 0,
  n.sim = 0,
  method = "gc",
  id = NA,
  handle.miss = 0,
  mloci = NA,
  sexid = NA
)
```

**Arguments**

y	Vector of trait values. For trait.type = "binomial", y must have values of 1 for event, 0 for no event.
geno	Matrix of alleles, such that each locus has a pair of adjacent columns of alleles, and the order of columns corresponds to the order of loci on a chromosome. If there are K loci, then ncol(geno) = 2*K. Rows represent alleles for each subject.
trait.type	Character string defining type of trait, with values of "gaussian", "binomial", "poisson", "ordinal".
offset	Vector of offset when trait.type = "poisson".
x.adj	Matrix of non-genetic covariates used to adjust the score statistics. Note that intercept should not be included, as it will be added in this function.
skip.haplo	Skip score statistics for haplotypes with frequencies < skip.haplo.
locus.label	Vector of labels for loci, of length K (see definition of geno matrix).
miss.val	Vector of codes for missing values of alleles.
n.sim	Number of simulations for empirical p-values. If n.sim=0, no empirical p-values are computed.
method	method of haplotype frequency estimation, "gc" or "hap".
id	an added option which contains the individual IDs.
handle.miss	flag to handle missing genotype data, 0=no, 1=yes.
mloci	maximum number of loci/sites with missing data to be allowed in the analysis.
sexid	flag to indicator sex for data from X chromosome, i=male, 2=female.

**Details**

This is a version which substitutes haplo.em.

**Value**

List with the following components:

**score.global** Global statistic to test association of trait with haplotypes that have frequencies  $\geq$  skip.haplo.

**df** Degrees of freedom for score.global.

**score.global.p** P-value of score.global based on chi-square distribution, with degrees of freedom equal to df.

**score.global.p.sim** P-value of score.global based on simulations (set equal to NA when n.sim=0).

**score.haplo** Vector of score statistics for individual haplotypes that have frequencies  $\geq$  skip.haplo.

**score.haplo.p** Vector of p-values for score.haplo, based on a chi-square distribution with 1 df.

**score.haplo.p.sim** Vector of p-values for score.haplo, based on simulations (set equal to NA when n.sim=0).

**score.max.p.sim** P-value of maximum score.haplo, based on simulations (set equal to NA when n.sim=0).

**haplotype** Matrix of haplotypes analyzed. The ith row of haplotype corresponds to the ith item of score.haplo, score.haplo.p, and score.haplo.p.sim.

**hap.prob** Vector of haplotype probabilities, corresponding to the haplotypes in the matrix haplotype.

**locus.label** Vector of labels for loci, of length K (same as input argument).

**n.sim** Number of simulations.

**n.val.global** Number of valid simulated global statistics.

**n.val.haplo** Number of valid simulated score statistics (score.haplo) for individual haplotypes.

hmht.control

*Controls for highlights*

---

## Description

Specification of highlights

## Usage

```
hmht.control(
  data = NULL,
  colors = NULL,
  yoffset = 0.25,
  cex = 1.5,
  boxed = FALSE
)
```

## Arguments

data	Data.
colors	Colors.
yoffset	Y offset.
cex	Scaling factor.
boxed	Label in box.

## Value

A list as above.

---

htr *Haplotype trend regression*

---

**Description**

Haplotype trend regression (with permutation)

**Usage**

```
htr(y, x, n.sim = 0)
```

**Arguments**

y	a vector of phenotype.
x	a haplotype table.
n.sim	the number of permutations.

**Value**

The returned value is a list containing:

- fthe F statistic for overall association
- pthe p value for overall association
- fvthe F statistics for individual haplotypes
- pithe p values for individual haplotypes

**Note**

adapted from emgi.cpp, a pseudorandom number seed will be added on.

hwe

*Hardy-Weinberg equilibrium test for a multiallelic marker*

---

**Description**

Hardy-Weinberg equilibrium test.

**Usage**

```
hwe(data, data.type = "allele", yates.correct = FALSE, miss.val = 0)
```

**Arguments**

**data** A rectangular data containing the genotype, or an array of genotype counts.

<code>data.type</code>	An option taking values "allele", "genotype", "count" if data is alleles, genotype or genotype count.
<code>yates.correct</code>	A flag indicating if Yates' correction is used for Pearson $\chi^2$ statistic.
<code>miss.val</code>	A list of missing values.

### Details

This function obtains Hardy-Weinberg equilibrium test statistics. It can handle data coded as allele numbers (default), genotype identifiers (by setting `data.type="genotype"`) and counts corresponding to individual genotypes (by setting `data.type="count"`) which requires that genotype counts for all  $n(n+1)$  possible genotypes, with  $n$  being the number of alleles.

For highly polymorphic markers when asymptotic results do not hold, please resort to `hwe.hardy`.

### Value

The returned value is a list containing:

**allele.freq** Frequencies of alleles

**x2** Pearson  $\chi^2$

**p.x2** p value for  $\chi^2$

**lrt** Log-likelihood ratio test statistic

**p.lrt** p value for lrt

**df** Degree(s) of freedom

**rho**  $\sqrt{\chi^2/N}$  the contingency table coefficient

## End(Not run)

```

---

hwe.cc	<i>A likelihood ratio test of population Hardy-Weinberg equilibrium for case-control studies</i>
--------	--

---

### Description

A likelihood ratio test of population Hardy-Weinberg equilibrium for case-control studies

### Usage

```
hwe.cc(model, case, ctrl, k0, initial1, initial2)
```

### Arguments

model	model specification, dominant, recessive.
case	a vector of genotype counts in cases.
ctrl	a vector of genotype counts in controls.
k0	prevalence of disease in the population.
initial1	initial values for beta, gamma, and q.
initial2	initial values for logit(p) and log(gamma).

### Details

This is a collection of utility functions. The null hypothesis declares that the proportions of genotypes are according to Hardy-Weinberg law, while under the alternative hypothesis, the expected genotype counts are according to the probabilities that particular genotypes are obtained conditional on the prevalence of disease in the population. In so doing, Hardy-Weinberg equilibrium is considered using both case and control samples but pending on the disease model such that 2-parameter multiplicative model is built on baseline genotype  $\alpha$ ,  $\alpha\beta$  and  $\alpha\gamma$ .

### Value

The returned value is a list with the following components.

**Cox** statistics under a general model  
**t2par** under the null hypothesis  
**t3par** under the alternative hypothesis  
**lrt.stat** the log-likelihood ratio statistic  
**pval** the corresponding p value

hwe.hardy

*Hardy-Weinberg equilibrium test using MCMC*

---

**Description**

Hardy-Weinberg equilibrium test by MCMC

**Usage**

```
hwe.hardy(a, alleles = 3, seed = 3000, sample = c(1000, 1000, 5000))
```

**Arguments**

<b>a</b>	an array containing the genotype counts, as integer.
<b>alleles</b>	number of allele at the locus, greater than or equal to 3, as integer.
<b>seed</b>	pseudo-random number seed, as integer.
<b>sample</b>	optional, parameters for MCMC containing number of chunks, size of a chunk and burn-in steps, as integer.

**Value**

The returned value is a list containing:

**method** Hardy-Weinberg equilibrium test using MCMC

**data.name** name of used data if x is given

**p.value** Monte Carlo p value

**p.value.se** standard error of Monte Carlo p value

**switches** percentage of switches (partial, full and altogether)

**Note**

Codes are commented for taking x a genotype object, as genotype to prepare a and alleles on the fly.

---

hwe.jags

*Hardy-Weinberg equilibrium test for a multiallelic marker using JAGS*

---

## Description

Hardy-Weinberg equilibrium test.

## Usage

```
hwe.jags(  
  k,  
  n,  
  delta = rep(1/k, k),  
  lambda = 0,  
  lambdamu = -1,  
  lambdasd = 1,  
  parms = c("p", "f", "q", "theta", "lambda"),  
  ...  
)
```

## Arguments

k	number of alleles.
n	a vector of $k(k+1)/2$ genotype counts.
delta	initial parameter values.
lambda	initial parameter values.
lambdamu	initial parameter values.
lambdasd	initial parameter values.
parms	monitored parameters.
...	parameters passed to jags, e.g., n.chains, n.burnin, n.iter.

## Details

This function performs Bayesian Hardy-Weinberg equilibrium test, which mirrors [hwe.hardy](#), another implementation for highly polymorphic markers when asymptotic results do not hold.

## Value

The returned value is a fitted model from `jags()`.

---

 invnormal

*Inverse normal transformation*

---

## Description

Inverse normal transformation

## Usage

```
invnormal(x)
```

## Arguments

x                      Data with missing values.

## Value

Transformed value.

## Examples

```

x <- 1:10
z <- invnormal(x)
plot(z,x,type="b")

```

---

inv\_chr\_pos\_a1\_a2      *Retrieval of chr:pos+a1/a2 according to SNP id*

---

### Description

This function obtains information embedded in unique identifiers.

### Usage

```
inv_chr_pos_a1_a2(chr_pos_a1_a2, prefix = "chr", seps = c(":", "_", "-"))
```

### Arguments

chr\_pos\_a1\_a2    SNP id.  
prefix            Prefix of the identifier.  
seps             Delimiters of fields.

### Value

A data.frame with the following variables.

**chr** Chromosome.

**pos** Position.

**a1** Allele 1.

**a2** Allele 2.

### Examples

```
# rs12075  
inv_chr_pos_a1_a2("chr1:159175354_A_G", prefix="chr", seps=c(":", "_", "-"))
```

---

ixy                      *Conversion of chrosome name from strings*

---

### Description

This function converts 1:22, X, Y back to 1:24.

### Usage

```
ixy(x)
```

### Arguments

x                      Chromosome name in strings

**Value**

As indicated.

---

KCC

*Disease prevalences in cases and controls*

---

**Description**

Disease prevalences in cases and controls

**Usage**

KCC(model, GRR, p1, K)

**Arguments**

model	disease model (one of "multiplicative", "additive", "recessive", "dominant", "overdominant").
GRR	genotype relative risk.
p1	disease allele frequency.
K	disease prevalence in the whole population.

**Details**

KCC calculates disease prevalences in cases and controls for a given genotype relative risk, allele frequency and prevalence of the disease in the whole population. It is used by tsc and pbsize2.

**Value**

A list of two elements,

**pprime** prevalence in cases.

**p** prevalence in controls.

# 6-6-2018 MRC-Epid JHZ

---

kin.morgan	<i>kinship matrix for simple pedigree</i>
------------	---

---

**Description**

kinship matrix according to Morgan v2.1.

**Usage**

```
kin.morgan(ped, verbose = FALSE)
```

**Arguments**

ped	individual's id, father's id and mother's id.
verbose	an option to print out the original pedigree.

**Value**

The returned value is a list containing:

**kin** the kinship matrix in vector form

**kin.matrix** the kinship matrix

**Note**

The input data is required to be sorted so that parents precede their children.

klem

*Haplotype frequency estimation based on a genotype table of two multiallelic markers*

---

### Description

Haplotype frequency estimation using expectation-maximization algorithm based on a table of genotypes of two multiallelic markers.

### Usage

```
klem(obs, k = 2, l = 2)
```

### Arguments

obs	a table of genotype counts.
k	number of alleles at marker 1.
l	number of alleles at marker 2.

The dimension of the genotype table should be  $k*(k+1)/2 \times l*(l+1)/2$ .  
Modified from 2ld.c.

### Value

The returned value is a list containing:

- h** haplotype Frequencies.
- l0** log-likelihood under linkage equilibrium.
- l1** log-likelihood under linkage disequilibrium.

### Author(s)

Jing Hua Zhao

---

`labelManhattan`*Annotate Manhattan or Miami Plot*

---

**Description**

Adds labels beside specified points on a Manhattan or Miami plot. Ideal for adding locus names to peaks. Currently only designed to work with [miamiplot2](#).

**Usage**

```
labelManhattan(
  chr,
  pos,
  name,
  gwas,
  gwasChrLab = "chr",
  gwasPosLab = "pos",
  gwasPLab = "p",
  gwasZLab = "NULL",
  chrmaxpos,
  textPos = 4,
  angle = 0,
  miamiBottom = FALSE
)
```

**Arguments**

<code>chr</code>	A vector of chromosomes for the markers to be labelled.
<code>pos</code>	A vector of positions on the chromosome for the markers to be labelled. These must correspond to markers in the GWAS dataset used to make the manhattan plot.
<code>name</code>	A vector of labels to be added next to the points specified by <code>chr</code> and <code>pos</code> .

gwas	The same GWAS dataset used to plot the existing Manhattan or Miami plot to be annotated.
gwasChrLab	The name of the column in gwas containing chromosome number. Defaults to "chr".
gwasPosLab	The name of the column in gwas containing position. Defaults to "pos".
gwasPLab	The name of the column in gwas containing p-values. Defaults to "p".
gwasZLab	The name of the column in gwas containing z-values. Defaults to "NULL".
chrmaxpos	Data frame containing x coordinates for chromosome start positions, generated by <a href="#">labelManhattan</a> .
textPos	An integer or vector dictating where the label should be plotted relative to each point. Good for avoiding overlapping labels. Provide an integer to plot all points in the same relative position or use a vector to specify position for each label. Passed to the 'pos' option of <a href="#">text</a> . Defaults to '4'.
angle	An integer or vector dictating the plot angle of the label for each point. Provide an integer to plot all points in the same relative position or use a vector to specify position for each label. Passed to the 'srt' option of <a href="#">text</a> . Defaults to '0'.
miamiBottom	If 'TRUE', labels will be plotted on the lower region of a Miami plot. If 'FALSE', labels will be plotted on the upper region. Defaults to 'FALSE'.

**Value**

Adds annotation to existing Manhattan or Miami plot

**Note**

Extended to handle extreme P values.

**Author(s)**

Jonathan Marten

**Examples**

```
## Not run:

               gwas1,chrmaxpos=chrmaxpos)
labelManhattan(geneLabels$chr,geneLabels$pos,geneLabels$geneName,gwas1,chrmaxpos=chrmaxpos)

## End(Not run)
```

**Description**

LD statistics for two SNPs.

**Usage**

LD22(h, n)

**Arguments**

**h** a vector of haplotype frequencies.  
**n** number of haplotypes.

**Details**

It is possible to perform permutation test of  $r^2$  by re-ordering the genotype through R's sample function, obtaining the haplotype frequencies by [gc.em](#) or [genecounting](#), supplying the estimated haplotype frequencies to the current function and record x2, and comparing the observed x2 and that from the replicates.

**Value**

The returned value is a list containing:

**h** the original haplotype frequency vector  
**n** the number of haplotypes  
**D** the linkage disequilibrium parameter  
**VarD** the variance of D  
**Dmax** the maximum of D  
**VarDmax** the variance of Dmax  
**Dprime** the scaled disequilibrium parameter  
**VarDprime** the variance of Dprime  
**x2** the Chi-squared statistic  
**lor** the log(OR) statistic  
**vlor** the var[log(OR)] statistic

**Note**

extracted from 2ld.c, worked 28/6/03, tables are symmetric do not fix, see kbyl below

LDk1

*LD statistics for two multiallelic markers*

---

**Description**

LD statistics for two multiallelic loci. For two diallelic makers, the familiar  $r^2$  has standard error  $seX2$ .

**Usage**

```
LDk1(n1 = 2, n2 = 2, h, n, optrho = 2, verbose = FALSE)
```

**Arguments**

n1	number of alleles at marker 1.
n2	number of alleles at marker 2.
h	a vector of haplotype frequencies.
n	number of haplotypes.
optrho	type of contingency table association, 0=Pearson, 1=Tschuprow, 2=Cramer (default).
verbose	detailed output of individual statistics.

**Value**

The returned value is a list containing:

- n1** the number of alleles at marker 1
- n2** the number of alleles at marker 2
- h** the haplotype frequency vector
- n** the number of haplotypes
- Dp** D'
- VarDp** variance of D'
- Dijtable** table of Dij
- VarDijtable** table of variances for Dij
- Dmaxtable** table of Dmax
- Dijptable** table of Dij'
- VarDijptable** table of variances for Dij'
- X2table** table of Chi-squares (based on Dij)
- ptable** table of p values
- x2** the Chi-squared statistic
- seX2** the standard error of x2/n
- rho** the measure of association
- seR** the standard error of rho
- optrho** the method for calculating rho
- klinfo** the Kullback-Leibler information

---

makeped

*A function to prepare pedigrees in post-MAKEPED format*

---

**Description**

A function to prepare pedigrees in post-MAKEPED format

**Usage**

```
makeped(
  pifile = "pedfile.pre",
  pofile = "pedfile.ped",
  auto.select = 1,
  with.loop = 0,
  loop.file = NA,
  auto.proband = 1,
  proband.file = NA
)
```

**Arguments**

pifile	input filename.
pofile	output filename.
auto.select	no loops in pedigrees and probands are selected automatically? 0=no, 1=yes.
with.loop	input data with loops? 0=no, 1=yes.
loop.file	filename containing pedigree id and an individual id for each loop, set if with.loop=1.
auto.proband	probands are selected automatically? 0=no, 1=yes.
proband.file	filename containing pedigree id and proband id, set if auto.proband=0 (not implemented).

**Details**

Many computer programs for genetic data analysis requires pedigree data to be in the so-called "post-MAKEPED" format. This function performs this translation and allows for some inconsistencies to be detected.

The first four columns of the input file contains the following information:

pedigree ID, individual ID, father's ID, mother's ID, sex

Either father's or mother's id is set to 0 for founders, i.e. individuals with no parents. Numeric coding for sex is 0=unknown, 1=male, 2=female. These can be followed by satellite information such as disease phenotype and marker information.

The output file has extra information extracted from data above.

Before invoking makeped, input file, loop file and proband file have to be prepared.

By default, auto.select=1, so translation proceeds without considering loops and proband statuses. If there are loops in the pedigrees, then set auto.select=0, with.loop=1, loop.file="filespec".

There may be several versions of makeped available, but their differences with this port should be minor.

### Note

```

---

masize

*Sample size calculation for mediation analysis*

---

### Description

The function computes sample size for regression problems where the goal is to assess mediation of the effects of a primary predictor by an intermediate variable or mediator.

### Usage

```
masize(model, opts, alpha = 0.025, gamma = 0.2)
```

### Arguments

model            "lineari", "logisticj", "poissonk", "coxll", where i,j,k,l range from 1 to 4,5,9,9, respectively.

opts	A list specific to the model
b1	regression coefficient for the primary predictor X1
b2	regression coefficient for the mediator X2
rho	correlation between X1 and X2
sdx1, sdx2	standard deviations (SDs) of X1 and X2
f1, f2	prevalence of binary X1 and X2
sd <sub>y</sub>	residual SD of the outcome for the linear model
p	marginal prevalence of the binary outcome in the logistic model
m	marginal mean of the count outcome in a Poisson model
f	proportion of uncensored observations for the Cox model
fc	proportion of observations censored early
alpha	one-sided type-I error rate
gamma	type-II error rate
ns	number of observations to be simulated
seed	random number seed

For linear model, the arguments are b2, rho, sdx2, sdy, alpha, and gamma. For cases CpBm and BpBm, set  $sdx2 = \sqrt{f2(1 - f2)}$ . Three alternative functions are included for the linear model. These functions make it possible to supply other combinations of input parameters affecting mediation:

b1*	coefficient for the primary predictor in the reduced model excluding the mediator (b1star)
b1	coefficient for the primary predictor in the full model including the mediator
PTE	proportion of the effect of the primary predictor explained by the mediator, defined as $(b1^* - b1)/b1^*$

These alternative functions for the linear model require specification of an extra parameter, but are provided for convenience, along with two utility files for computing PTE and b1\* from the other parameters. The required arguments are explained in comments within the R code.

alpha	Type-I error rate, one-sided.
gamma	Type-II error rate.

## Details

Mediation has been thought of in terms of the proportion of effect explained, or the relative attenuation of b1, the coefficient for the primary predictor X1, when the mediator, X2, is added to the model. The goal is to show that b1\*, the coefficient for X1 in the reduced model (i.e., the model with only X1, differs from b1, its coefficient in the full model (i.e., the model with both X1 and the mediator X2. If X1 and X2 are correlated, then showing that b2, the coefficient for X2, differs from zero is equivalent to showing b1\* differs from b1. Thus the problem reduces to detecting an effect of X2, controlling for X1. In short, it amounts to the more familiar problem of inflating sample size to account for loss of precision due to adjustment for X1.

The approach here is to approximate the expected information matrix from the regression model including both X1 and X2, to obtain the expected standard error of the estimate of b2, evaluated at the MLE. The sample size follows from comparing the Wald test statistic (i.e., the ratio of the estimate of b2 to its SE) to the standard normal distribution, with the expected value of the numerator and denominator of the statistic computed under the alternative hypothesis. This reflects the Wald test for the statistical significance of a coefficient implemented in most regression packages.

The function provides methods to calculate sample sizes for the mediation problem for linear, logistic, Poisson, and Cox regression models in four cases for each model:

CpCm	continuous primary predictor, continuous mediator
BpCm	binary primary predictor, continuous mediator
CpBm	continuous primary predictor, binary mediator
BpBm	binary primary predictor, binary mediator

The function is also generally applicable to the analogous problem of calculating sample size adequate to detect the effect of a primary predictor in the presence of confounding. Simply treat X2 as the primary predictor and consider X1 the confounder.

For linear model, a single function, `linear`, implements the analytic solution for all four cases, based on Hsieh et al., is to inflate sample size by a variance inflation factor,  $1/(1 - \rho^2)$ , where  $\rho$  is the correlation of X1 and X2. This also turns out to be the analytic solution in cases CpCm and BpCm for the Poisson model, and underlies approximate solutions for the logistic and Cox models. An analytic solution is also given for cases CpBm and BpBm for the Poisson model. Since analytic solutions are not available for the logistic and Cox models, a simulation approach is used to obtain the expected information matrix instead.

For logistic model, the approximate solution due to Hsieh is implemented in the function `logistic.approx`, and can be used for all four cases. Arguments are `p`, `b2`, `rho`, `sdX2`, `alpha`, and `gamma`. For a binary mediator with prevalence `f2`, `sdX2` should be reset to  $\sqrt{f2(1 - f2)}$ . Simulating the information matrix of the logistic model provides somewhat more accurate sample size estimates than the Hsieh approximation. The functions for cases CpCm, BpCm, CpBm, and BpBm are respectively `logistic.ccs`, `logistic.bcs`, `logistic.cbs`, and `logistic.bbs`, as for the Poisson and Cox models. Arguments for these functions include `p`, `b1`, `sdX1` or `f1`, `b2`, `sdX2` or `f2`, `rho`, `alpha`, `gamma`, and `ns`. As in other functions, `sdX1`, `sdX2`, `alpha`, and `gamma` are set to the defaults listed above. These four functions call two utility functions, `getb0` (to calculate the intercept parameter from the others) and `antilogit`, which are supplied.

For Poisson model, The function implementing the approximate solution based on the variance inflation factor is `poisson.approx`, and can be used for all four cases. Arguments are `EY` (the marginal mean of the Poisson outcome), `b2`, `sdX2`, `rho`, `alpha` and `gamma`, with `sdX2`, `alpha` and `gamma` set to the usual defaults; use `sdX2 = \sqrt{f2(1 - f2)}` for a binary mediator with prevalence `f2` (cases CpBm and BpBm). For cases CpCm and BpCm (continuous mediators), the approximate formula is also the analytic solution. For these cases, we supply redundant functions `poisson.cc` and `poisson.bc`, with the same arguments and defaults as for `poisson.approx` (it's the same function). For the two cases with binary mediators, the functions are `poisson.cb` and `poisson.bb`. In addition to `m`, `b2`, `f2`, `rho`, `alpha`, and `gamma`, `b1` and `sdX1` or `f1` must be specified. Defaults are as usual. Functions using simulation for the Poisson model are available: `poisson.ccs`, `poisson.bcs`, `poisson.cbs`, and `poisson.bbs`. As in the logistic case, these require arguments `b1` and `sdX1` or `f1`. For this case, however, the analytic functions are faster, avoid simulation error, and should be used. We include these functions as templates that could be adapted to other joint predictor distributions. For Cox model,

the function implementing the approximate solution, using the variance inflation factor and derived by Schmoor et al., is `cox.approx`, and can be used for all four cases. Arguments are `b2`, `sdx2`, `rho`, `alpha`, `gamma`, and `f`. For binary X2 set  $\text{sdx2} = \sqrt{f^2(1-f^2)}$ . The approximation works very well for cases CpCm and BpCm (continuous mediators), but is a bit less accurate for cases CpBm and BpBm (binary mediators). We get some improvement for those cases using the simulation approach. This approach is implemented for all four, as functions `cox.ccs`, `cox.bcs`, `cox.cbs`, and `cox.bbs`. Arguments are `b1`, `sdx1` or `f1`, `b2`, `sdx2` or `f2`, `rho`, `alpha`, `gamma`, `f`, and `ns`, with defaults as described above. Slight variants of these functions, `cox.ccs2`, `cox.bcs2`, `cox.cbs2`, and `cox.bbs2`, make it possible to allow for early censoring of a fraction `fc` of observations; but in our experience this has virtually no effect, even with values of `fc` of 0.5. The default for `fc` is 0.

A summary of the arguments is as follows, noting that additional parameter `seed` can be supplied for simulation-based method.

model	arguments	description
linear1	b2, rho, sdx2, sdy	linear
linear2	b1star, PTE, rho, sdx1, sdy	lineara
linear3	b1star, b2, PTE, sdx1, sdx2, sdy	linearb
linear4	b1star, b1, b2, sdx1, sdx2, sdy	linearc
logistic1	p, b2, rho, sdx2	logistic.approx
logistic2	p, b1, b2, rho, sdx1, sdx2, ns	logistic.ccs
logistic3	p, b1, f1, b2, rho, sdx2, ns	logistic.bcs
logistic4	p, b1, b2, f2, rho, sdx1, ns	logistic.cbs
logistic5	p, b1, f1, b2, f2, rho, ns	logistic.bbs
poisson1	m, b2, rho, sdx2	poisson.approx
poisson2	m, b2, rho, sdx2	poisson.cc
poisson3	m, b2, rho, sdx2	poisson.bc
poisson4	m, b1, b2, f2, rho, sdx1	poisson.cb
poisson5	m, b1, f1, b2, f2, rho	poisson.bb
poisson6	m, b1, b2, rho, sdx1, sdx2, ns	poisson.ccs
poisson7	m, b1, f1, b2, rho, sdx2, ns	poisson.bcs
poisson8	m, b1, b2, f2, rho, sdx1, ns	poisson.cbs
poisson9	m, b1, f1, b2, f2, rho, ns	poisson.bbs
cox1	b2, rho, f, sdx2	cox.approx
cox2	b1, b2, rho, f, sdx1, sdx2, ns	cox.ccs
cox3	b1, f1, b2, rho, f, sdx2, ns	cox.bcs
cox4	b1, b2, f2, rho, f, sdx1, ns	cox.cbs
cox5	b1, f1, b2, f2, rho, f, ns	cox.bbs
cox6	b1, b2, rho, f, fc, sdx1, sdx2, ns	cox.ccs2
cox7	b1, f1, b2, rho, f, fc, sdx2, ns	cox.bcs2
cox8	b1, b2, f2, rho, f, fc, sdx1, ns	cox.cbs2
cox9	b1, f1, b2, f2, rho, f, fc, ns	cox.bbs2

**Value**

A short description of model (desc, b=binary, c=continuous, s=simulation) and sample size (n). In the case of Cox model, number of events (d) is also indicated.

MCMCgrm

*Mixed modeling with genetic relationship matrices*

---

## Description

Mixed modeling with genomic relationship matrix. This is appropriate with relationship matrix derived from family structures or unrelated individuals based on whole genome data.

## Usage

```
MCMCgrm(
  model,
  prior,
  data,
  GRM,
  eps = 0,
  n.thin = 10,
  n.burnin = 3000,
  n.iter = 13000,
  ...
)
```

## Arguments

model	statistical model.
prior	a list of priors for parameters in the model above.
data	a data.frame containing outcome and covariates.
GRM	a relationship matrix.
eps	a small number added to the diagonal of the a nonpositive definite GRM.
n.thin	thinning parameter in the MCMC.
n.burnin	the number of burn-in's.
n.iter	the number of iterations.
...	other options as appropriate for MCMCglmm.

## Details

The function was created to address a number of issues involving mixed modelling with family data or population sample with whole genome data. First, the implementation will shed light on the uncertainty involved with polygenic effect in that posterior distributions can be obtained. Second, while the model can be used with the MCMCglmm package there is often issues with the specification of pedigree structures but this is less of a problem with genetic relationship matrices. We can use established algorithms to generate kinship or genomic relationship matrix as input to the MCMCglmm function. Third, it is more intuitive to specify function arguments in line with other packages such as R2OpenBUGS, R2jags or glmmBUGS. In addition, our experiences of tuning the model would help to reset the input and default values.

## Value

The returned value is an object as generated by MCMCglmm.

---

METAL\_forestplot

*forest plot as R/meta's forest for METAL outputs*

---

## Description

This functions takes a meta-data from METAL (tbl) and data from contributing studies (all) for forest plot. It also takes a SNPID-rsid mapping (rsid) as contributing studies often involve discrepancies in rsid so it is appropriate to use SNPID, i.e., chr:pos\_A1\_A2 (A1<=A2).

## Usage

```
METAL_forestplot(tbl, all, rsid, package = "meta", split = FALSE, ...)
```

## Arguments

tbl	Meta-analysis summary statistics.
all	statistics from all contributing studies.
rsid	SNPID-rsid mapping file.
package	style of plot as in meta, rmeta or forestplot.
split	when TRUE, individual prot-MarkerName.pdf will be generated.
...	Additional arguments to meta::forest.

## Details

The study-specific and total sample sizes (N) can be customised from METAL commands. By default, the input triplets each contain a 'MarkerName' variable which is the unique SNP identifier (e.g., chr:pos:a1:a2) and the 'tbl' argument has variables 'A1' and 'A2' as produced by METAL while the 'all' argument has 'EFFECT\_ALLELE' and 'REFERENCE\_ALLELE' as with a 'study' variable indicating study name. Another variable common the 'tbl' and 'all' is 'prot' variable as the function was developed in a protein based meta-analysis. From these all information is in place for generation of a list of Forest plots through a batch run.

```
CUSTOMVARIABLE N  
LABEL N as N  
WEIGHTLABEL N
```

## Value

It will generate a forest plot specified by pdf for direction-adjusted effect sizes.

metap

*Meta-analysis of p values*

---

### Description

This function is the method of meta-analysis used in the Genetic Investigation of ANThropometric Traits (GIANT) consortium, which is based on normal approximation of p values and weighted by sample sizes from individual studies.

### Usage

```
metap(data, N, verbose = "Y", prefixp = "p", prefixn = "n")
```

### Arguments

data	data frame.
N	Number of studies.
verbose	Control of detailed output.
prefixp	Prefix of p value, with default value "p".
prefixn	Preifx of sample size, with default value "n".

### Value

**x2** Fisher's chi-squared statistics.

**p** P values from Fisher's method according to chi-squared distribution with  $2*N$  degree(s) of freedom.

**z** Combined z value.

**p1** One-sided p value.

**p2** Two-sided p value.

## End(Not run)

```

**Description**

Given  $k = n$  studies with  $b_1, \dots, b_N$  being  $\beta$ 's and  $se_1, \dots, se_N$  standard errors from regression, the fixed effects model uses inverse variance weighting such that  $w_1 = 1/se_1^2, \dots, w_N = 1/se_N^2$  and the combined  $\beta$  as the weighted average,  $\beta_f = (b_1 * w_1 + \dots + b_N * w_N)/w$ , with  $w = w_1 + \dots + w_N$  being the total weight, the se for this estimate is  $se_f = \sqrt{1/w}$ . A normal z-statistic is obtained as  $z_f = \beta_f/se_f$ , and the corresponding p value  $p_f = 2 * pnorm(-abs(z_f))$ . For the random effects model, denote  $q_w = w_1 * (b_1 - \beta_f)^2 + \dots + w_N * (b_N - \beta_f)^2$  and  $dl = \max(0, (q_w - (k - 1))/(w - (w_1^2 + \dots + w_N^2)/w))$ , corrected weights are obtained such that

$w_{1c} = 1/(1/w_1 + dl), \dots, w_{Nc} = 1/(1/w_N + dl)$ , totaling  $w_c = w_{1c} + \dots + w_{Nc}$ . The combined  $\beta$  and se are then  $\beta_r = (b_1 * w_{1c} + \dots + b_N * w_{Nc})/w_c$  and  $se_r = \sqrt{(1/w_c)}$ , leading to a z-statistic  $z_r = \beta_r/se_r$  and a p-value  $p_r = 2 * pnorm(-abs(z_r))$ . Moreover, a p-value testing for heterogeneity is  $p_{heter} = pchisq(q_w, k - 1, lower.tail = FALSE)$ .

### Usage

```
metareg(data, N, verbose = "Y", prefixb = "b", prefixse = "se")
```

### Arguments

data	Data frame to be used.
N	Number of studies.
verbose	A control for screen output.
prefixb	Prefix of estimate; default value is "b".
prefixse	Prefix of standard error; default value is "se". The function accepts a wide format data with estimates as $b_1, \dots, b_N$ and standard errors as $se_1, \dots, se_N$ . More generally, they can be specified by prefixes in the function argument.

### Value

The returned value is a data frame with the following variables:

- p\_f** P value (fixed effects model)
- p\_r** P value (random effects model)
- beta\_f** regression coefficient
- beta\_r** regression coefficient
- se\_f** standard error
- se\_r** standard error
- z\_f** z value
- z\_r** z value
- p\_heter** heterogeneity test p value
- i2**  $I^2$  statistic
- k** No of tests used
- eps** smallest double-precision number

mht.control

*Controls for mhtplot*

---

## Description

Parameter specification through function

## Usage

```
mht.control(
  type = "p",
  usepos = FALSE,
  logscale = TRUE,
  base = 10,
  cutoffs = NULL,
  colors = NULL,
  labels = NULL,
  srt = 45,
  gap = NULL,
  cex = 0.4,
  yline = 3,
  xline = 3
)
```

## Arguments

type	Type of plot.
usepos	A flag.
logscale	A flag for log-scale.
base	Base of log.

cutoffs	Cutoffs of P-value, etc.
colors	Colours for chromosomes.
labels	Labels for chromosomes.
srt	Rotation degrees.
gap	Gap between data points.
cex	Scaling factor of data points.
yline	Vertical adjustment.
xline	Horiztonal adjustment.

**Value**

A list as above.

---

mhtplot

*Manhattan plot*

---

**Description**

To generate Manhattan plot, e.g., of genomewide significance (p values) and a random variable that is uniformly distributed. By default, a log10-transformation is applied. Note that with real chromosomal positions, it is also appropriate to plot and some but not all chromosomes.

**Usage**

```
mhtplot(data, control = mht.control(), hcontrol = hmht.control(), ...)
```

**Arguments**

data	a data frame with three columns representing chromosome, position and p values
control	A control function named mht.control() with the following arguments, <ul style="list-style-type: none"> <li>• type a flag with value "p" or "l" indicating if points or lines are to be drawn.</li> <li>• usepos a flag to use real chromosomal positions as composed to ordinal positions with default value FALSE</li> <li>• logscale a flag to indicate if p value is to be log-transformed with default value TRUE</li> <li>• base the base of the logarithm with default value 10</li> <li>• cutoffs the cut-offs where horizontal line(s) are drawn with default value NULL</li> <li>• colors the color for different chromosome(s), and random if unspecified with default values NULL</li> <li>• labels labels for the ticks on x-axis with default value NULL</li> <li>• srt degree to which labels are rotated with default value of 45</li> <li>• gap gap between chromosomes with default value NULL</li> </ul>

- cex cex for the data points
  - yline Margin line position
  - xline Margin line position
- hcontrol A control function named hmht.control() with the following arguments,
- data. chunk of data to be highlighted with default value NULL
  - colors. colors for annotated genes
  - yoffset. offset above the data point showing most significant p value with default value 0.5
  - cex shrinkage factor for data points with default value 1.5
  - boxed if the label for the highlited region with default value FALSE
- ... other options in compatible with the R plot function.

### Details

It is possible to specify options such as xlab and ylim when the plot is requested for data in other context.

### Value

The plot is shown on or saved to the appropriate device.

---

mhtplot.trunc	<i>Truncated Manhattan plot</i>
---------------	---------------------------------

---

## Description

To generate truncated Manhattan plot, e.g., of genomewide significance (P values) or a random variable that is uniformly distributed.

## Usage

```
mhtplot.trunc(  
  x,  
  chr = "CHR",  
  bp = "BP",  
  p = NULL,  
  log10p = NULL,  
  z = NULL,  
  snp = "SNP",  
  col = c("gray10", "gray60"),  
  chrlabs = NULL,  
  suggestiveline = -log10(1e-05),  
  genomewideline = -log10(5e-08),  
  highlight = NULL,  
  annotatelog10P = NULL,  
  annotateTop = FALSE,  
  cex.mtext = 1.5,  
  cex.text = 0.7,  
  mtext.line = 2,  
  y.ax.space = 5,  
  y.brk1 = NULL,  
  y.brk2 = NULL,  
  trunc.yaxis = TRUE,  
  cex.axis = 1.2,  
  delta = 0.05,  
  ...  
)
```

## Arguments

x	A data.frame.
chr	Chromosome.
bp	Position.
p	p values, e.g., "1.23e-600".
log10p	log10(p).
z	z statistic, i.e., BETA/SE.

snp	SNP. Pending on the setup it could either of variant or gene ID(s).
col	Colours.
chrlabs	Chromosome labels, 1,2,...22,23,24,25.
suggestiveline	Suggestive line.
genomewideline	Genomewide line.
highlight	A list of SNPs to be highlighted.
annotatelog10P	Threshold of $-\log_{10}(P)$ to annotate.
annotateTop	Annotate top.
cex.mtext	axis label extension factor.
cex.text	SNP label extension factor.
mtext.line	position of the y lab.
y.ax.space	interval of ticks of the y axis.
y.brk1	lower $-\log_{10}(P)$ break point.
y.brk2	upper $-\log_{10}(P)$ break point.
trunc.yaxis	do not truncate y-axisx when FALSE.
cex.axis	extension factor for x-, y-axis.
delta	a value to enable column(s) of red points.
...	other options.

### Details

The rationale of this function is to extend mhtplot() to handle extremely small p values as often seen from a protein GWAS. Optionally, the function also draws an ordinary Manhattan plot.

### Value

The plot is shown on or saved to the appropriate device.

---

mhtplot2

*Manhattan plot with annotations*

---

## Description

To generate Manhattan plot with annotations. The function is generic and for instance could be used for genomewide p values or any random variable that is uniformly distributed. By default, a log10-transformation is applied. Note that with real chromosomal positions, it is also appropriate to plot and some but not all chromosomes.

## Usage

```
mhtplot2(data, control = mht.control(), hcontrol = hmht.control(), ...)
```

## Arguments

data	a data frame with three columns representing chromosome, position and p values.
control	A control function named <code>mht.control()</code> with the following arguments. <ul style="list-style-type: none"> <li>• <code>type</code> a flag with value "p" or "l" indicating if points or lines are to be drawn.</li> <li>• <code>usepos</code> a flag to use real chromosomal positions as composed to ordinal positions with default value FALSE</li> <li>• <code>logscale</code> a flag to indicate if p value is to be log-transformed with default value TRUE</li> </ul>

- base the base of the logarithm with default value 10
  - cutoffs the cut-offs where horizontal line(s) are drawn with default value NULL
  - colors the color for different chromosome(s), and random if unspecified with default values NULL
  - labels labels for the ticks on x-axis with default value NULL
  - srt degree to which labels are rotated with default value of 45
  - gap gap between chromosomes with default value NULL
  - cex cex for the data points
  - yline Margin line position
  - xline Margin line position
- hcontrol A control function named hmht.control() with the following arguments.
- data chunk of data to be highlighted with default value NULL
  - colors colors for annotated genes
  - yoffset offset above the data point showing most significant p value with default value 0.5
  - cex shrinkage factor for data points with default value 1.5
  - boxed if the label for the highlighted region with default value FALSE
- ... other options in compatible with the R plot function.

### Details

It is possible to specify options such as xlab, ylim and font family when the plot is requested for data in other context.

To maintain back compatibility options as in `mhtplot` are used. The positions of the horizontal labels are now in the middle rather than at the beginning of their bands in the plot.

### Value

The plot is shown on or saved to the appropriate device.

par(opar)

## End(Not run)

```

**Description**

This command reads outputs from hap session that uses multiple imputations, i.e. -mi# option. To simplify matters it assumes -ss option is specified together with -mi option there.

**Usage**

```

mia(
  hapfile = "hap.out",
  assfile = "assign.out",
  miafile = "mia.out",
  so = 0,
  ns = 0,
  mi = 0,

```

```

    allsnps = 0,
    sas = 0
)

```

### Arguments

hapfile	hap haplotype output file name.
assfile	hap assignment output file name.
miafile	mia output file name.
so	to generate results according to subject order.
ns	do not sort in subject order.
mi	number of multiple imputations used in hap.
allsnps	all loci are SNPs.
sas	produce SAS data step program.

### Details

This is a very naive version of MIANALYZE, but can produce results for PROC MIANALYZE of SAS.

It simply extracts outputs from hap.

### Value

The returned value is a list.

### Note

adapted from hap, in fact cline.c and cline.h are not used. keywords utilities

# system("csh")

## End(Not run)

```

---

miamiplot

*Miami plot*

---

## Description

The function allows for contrast of genomewide P values from two GWASs. It is conceptually simpler than at the first sight since it involves only one set of chromosomal positions.

## Usage

```

miamiplot(
  x,
  chr = "CHR",
  bp = "BP",
  p = "P",
  pr = "PR",
  snp = "SNP",
  col = c("midnightblue", "chartreuse4"),
  col2 = c("royalblue1", "seagreen1"),
  ymax = NULL,
  highlight = NULL,
  highlight.add = NULL,
  pch = 19,
  cex = 0.75,
  cex.lab = 1,
  xlab = "Chromosome",
  ylab = "-log10(P) [y>0]; log10(P) [y<0]",
  lcols = c("red", "black"),
  lwds = c(5, 2),
  ltys = c(1, 2),
  main = "",
  ...
)

```

**Arguments**

x	Input data.
chr	Chromosome.
bp	Position.
p	P value.
pr	P value of the other GWAS.
snp	Marker.
col	Colors.
col2	Colors.
ymax	Max y.
highlight	Highlight flag.
highlight.add	Highlight meta-data.
pch	Symbol.
cex	cex.
cex.lab	cex for labels.
xlab	Label for x-axis.
ylab	Label for y-axis.
lcols	Colors.
lwds	lwd.
lty	lty.
main	Main title.
...	Additional options.

**Value**

None.

**Examples**

```
## Not run:  
mhtdata <- within(mhtdata, {pr=p})  
miamiplot(mhtdata, chr="chr", bp="pos", p="p", pr="pr", snp="rsn")  
  
## End(Not run)
```

---

`miamiplot2`*Miami Plot*

---

### Description

Creates a Miami plot to compare results from two genome-wide association analyses.

### Usage

```
miamiplot2(  
  gwas1,  
  gwas2,  
  name1 = "GWAS 1",  
  name2 = "GWAS 2",  
  chr1 = "chr",  
  chr2 = "chr",  
  pos1 = "pos",  
  pos2 = "pos",  
  p1 = "p",  
  p2 = "p",  
  z1 = NULL,  
  z2 = NULL,  
  sug = 1e-05,  
  sig = 5e-08,  
  pcutoff = 0.1,  
  topcols = c("green3", "darkgreen"),  
  botcols = c("royalblue1", "navy"),  
  yAxisInterval = 5  
)
```

### Arguments

<code>gwas1</code>	The first of two GWAS datasets to plot, in the upper region.
<code>gwas2</code>	The second of two GWAS datasets to plot, in the lower region.
<code>name1</code>	The name of the first dataset, plotted above the upper plot region. Defaults to "GWAS 1".
<code>name2</code>	The name of the second dataset, plotted below the lower plot region. Defaults to "GWAS 2".
<code>chr1</code>	The name of the column containing chromosome number in <code>gwas1</code> . Defaults to "chr".
<code>chr2</code>	The name of the column containing chromosome number in <code>gwas2</code> . Defaults to "chr".
<code>pos1</code>	The name of the column containing SNP position in <code>gwas1</code> . Defaults to "pos".
<code>pos2</code>	The name of the column containing SNP position in <code>gwas2</code> . Defaults to "pos".
<code>p1</code>	The name of the column containing p-values in <code>gwas1</code> . Defaults to "p".

p2	The name of the column containing p-values in gwas2. Defaults to "p".
z1	The name of the column containing z-values in gwas1. Defaults to "NULL".
z2	The name of the column containing z-values in gwas2. Defaults to "NULL".
sug	The threshold for suggestive significance, plotted as a light grey dashed line.
sig	The threshold for genome-wide significance, plotted as a dark grey dashed line.
pcutoff	The p-value threshold below which SNPs will be ignored. Defaults to 0.1. It is not recommended to set this higher as it will narrow the central gap between the two plot region where the chromosome number is plotted.
topcols	A vector of two colours to plot alternating chromosomes in for the upper plot. Defaults to green3 and darkgreen.
botcols	A vector of two colours to plot alternating chromosomes in for the lower plot. Defaults to royalblue1 and navy.
yAxisInterval	The interval between tick marks on the y-axis. Defaults to 5, 2 may be more suitable for plots with larger minimum p-values.

### Value

In addition to creating a Miami plot, the function returns a data frame containing x coordinates for chromosome start positions (required for [labelManhattan](#))

### Note

Extended to handle extreme P values.

### Author(s)

Jonathan Marten

### Examples

```
## Not run:
# miamiplot2(gwas1, gwas2)
# chrmaxpos <- miamiplot2(gwas1, gwas2)
gwas <- within(mhtdata[c("chr", "pos", "p")], {z=qnorm(p/2)})
chrmaxpos <- miamiplot2(gwas, gwas, name1="Batch 2", name2="Batch 1", z1="z", z2="z")
labelManhattan(chr=c(2, 16), pos=c(226814165, 52373776), name=c("AnonymousGene", "FTO"),
               gwas, gwasZLab="z", chrmaxpos=chrmaxpos)

## End(Not run)
```

---

mr *Mendelian randomization analysis*

---

## Description

The function initially intends to rework on GSMR outputs, but it would be appropriate for general use.

## Usage

```
mr(data, X, Y, alpha = 0.05, other_plots = FALSE)
```

## Arguments

data	Data to be used.
X	Exposure.
Y	Outcome.
alpha	type I error rate for confidence intervals.
other_plots	To add funnel and forest plots.

## Value

The result and plots.

## Examples

```

---

mr_forestplot	<i>Mendelian Randomization forest plot</i>
---------------	--

---

## Description

Mendelian Randomization forest plot

## Usage

```
mr_forestplot(dat, sm = "", title = "", ...)
```

## Arguments

dat	A data.frame with outcome id, effect size and standard error.
sm	Summary measure such as OR, RR, MD.
title	Title of the meta-analysis.
...	Other options for meta::forest().

## Details

This is a wrapper of meta::forest() for multi-outcome Mendelian Randomization. It allows for the flexibility of both binary and continuous outcomes with and without summary level statistics.

## Examples

```

mtdt

*Transmission/disequilibrium test of a multiallelic marker*

---

## Description

This function calculates transmission-disequilibrium statistics involving multiallelic marker.

## Usage

```
mtdt(x, n.sim = 0)
```

## Arguments

x	the data table.
n.sim	the number of simulations.

## Details

Inside the function are `tril` and `triu` used to obtain lower and upper triangular matrices.

## Value

It returned list contains the following components:

**SE** Spielman-Ewens Chi-square from the observed data

**ST** Stuart or score Statistic from the observed data

**pSE** the simulated p value

**sSE** standard error of the simulated p value  
**pST** the simulated p value  
**sST** standard error of the simulated p value

### Author(s)

Mike Miller, Jing Hua Zhao

mtdt2	<i>Transmission/disequilibrium test of a multiallelic marker by Bradley-Terry model</i>
-------	---

---

### Description

This function calculates transmission-disequilibrium statistics involving multiallelic marker according to Bradley-Terry model.

### Usage

```
mtdt2(x, verbose = TRUE, n.sim = NULL, ...)
```

### Arguments

<code>x</code>	the data table.
<code>verbose</code>	To print out test statistics if TRUE.
<code>n.sim</code>	Number of simulations.
<code>...</code>	other options compatible with the BTm function.

### Value

It returned list contains the following components:

**c2b** A data frame in four-column format showing transmitted vs nontransmitted counts.

**BTm** A fitted Bradley-Terry model object.

**X2** Allele-wise, genotype-wise and goodness-of-fit Chi-squared statistics.

**df** Degrees of freedom.

**p** P value.

**pn** Monte Carlo p values when n.sim is specified.

muvar

*Means and variances under 1- and 2- locus (biallelic) QTL model***Description**

Function `muvar()` gives means and variances under 1-locus and 2-locus QTL model (simple); in the latter case it gives results from different avenues. This function is included for experimental purpose and yet to be generalized.

**Usage**

```
muvar(
  n.loci = 1,
  y1 = c(0, 1, 1),
  y12 = c(1, 1, 1, 1, 1, 0, 0, 0, 0),
  p1 = 0.99,
  p2 = 0.9
)
```

**Arguments**

n.loci	number of loci, 1=single locus, 2=two loci.
y1	the genotypic means of aa, Aa and AA.
y12	the genotypic means of aa, Aa and AA at the first locus and bb, Bb and BB at the second locus.
p1	the frequency of the lower allele, or the that for the first locus under a 2-locus model.
p2	the frequency of the lower allele at the second locus.

**Value**

Currently it does not return any value except screen output; the results can be kept via R's sink() command or via modifying the C/R codes.

**Note**

Adapted from an earlier C program written for the above book.

**Author(s)**

Jing Hua Zhao

---

mvmeta

---

*Multivariate meta-analysis based on generalized least squares*

---

**Description**

This function accepts a data matrix of parameter estimates and their variance-covariance matrix from individual studies and obtain a generalized least squares (GLS) estimate and heterogeneity statistic.

**Usage**

```
mvmeta(b, V)
```

**Arguments**

**b** the parameter estimates.  
**V** the triangular variance-covariance matrix.

**Details**

For instance, this would be appropriate for combining linear correlation coefficients of single nucleotide polymorphisms (SNPs) for a given region.

**Value**

The returned value is a list containing:

**d** the compact parameter estimates  
**Psi** the compact covariance-covariance matrix  
**X** the design matrix  
**beta** the pooled parameter estimates  
**cov.beta** the pooled variance-covariance matrix  
**X2** the Chi-squared statistic for heterogeneity  
**df** the degrees(s) of freedom  
**p** the p value

## End(Not run)

```

**Description**

This function implements Long et al. (1997) statistics for population-based association design. This is based on a contingency table test and accurate level of significance can be obtained by Fisher's exact test.

**Usage**

```
pbsize(kp, gamma = 4.5, p = 0.15, alpha = 5e-08, beta = 0.2)
```

**Arguments**

kp	population disease prevalence.
gamma	genotype relative risk assuming multiplicative model.
p	frequency of disease allele.
alpha	type I error rate.
beta	type II error rate.

**Value**

The returned value is scalar containing the required sample size.

**Author(s)**

```

## Description

This is a revised version of [pbsize](#) which is appropriate for a case-control design under a range of disease models. Essentially, for given sample size(s), a proportion of which (fc) being cases, the function calculates power estimate for a given type I error (alpha), genotype relative risk (gamma), frequency of the risk allele (p), the prevalence of disease in the population (kp) and optionally a disease model (model). A major difference would be the consideration of case/control ascertainment in [pbsize](#).

**Usage**

```
pysize2(  
  N,  
  fc = 0.5,  
  alpha = 0.05,  
  gamma = 4.5,  
  p = 0.15,  
  kp = 0.1,  
  model = "additive"  
)
```

**Arguments**

N	The sample size.
fc	The proportion of cases in the sample.
alpha	Type I error rate.
gamma	The genotype relative risk (GRR).
p	Frequency of the risk allele.
kp	The prevalence of disease in the population.
model	Disease model, i.e., "multiplicative", "additive", "dominant", "recessive", "overdominant".

**Details**

Internally, the function obtains a baseline risk to make the disease model consistent with  $K_p$  as in `tscc` and should produce accurate power estimate. Note it provides power estimates for given sample size(s) only.

**Value**

The returned value is the power for the specified design.

**Note**

Why is the comparison with `power.casectl` so bad?

**Author(s)**

Jing Hua Zhao

**See Also**

The design follows that of `pysize`.

**Examples**

```
## Not run:
# single calc
m <- c("multiplicative","recessive","dominant","additive","overdominant")
for(i in 1:5) print(pbsize2(N=50,alpha=5e-2,gamma=1.1,p=0.1,kp=0.1, model=m[i]))

# for a range of sample sizes
pbsize2(p=0.1, N=c(25,50,100,200,500), gamma=1.1, kp=.1, alpha=5e-2, model='r')

# create a power table

## End(Not run)
```

---

pedtodot

*Converting pedigree(s) to dot file(s)*

---

**Description**

This function converts GAS or LINKAGE formatted pedigree(s) into .dot file for each pedigree to be used by dot in graphviz, which is a flexible package for graphics freely available.

**Usage**

```
pedtodot(
  pedfile,
  makeped = FALSE,
  sink = TRUE,
  page = "B5",
```

```

url = "https://jinghuazhao.github.io/",
height = 0.5,
width = 0.75,
rotate = 0,
dir = "none"
)

```

### Arguments

pedfile	a pedigree file in GAS or LINKAGE format, note if individual's ID is character then it is necessary to specify as.is=T in the read.table command.
makeped	a logical variable indicating if the pedigree file is post-makeped.
sink	a logical variable indicating if .dot file(s) are created.
page	a string indicating the page size, e.g, A4, A5, B5, Legal, Letter, Executive, "x,y", where x, y is the customized page size.
url	Unified Resource Locator (URL) associated with the diagram(s).
height	the height of node(s).
width	the width of node(s).
rotate	if set to 90, the diagram is in landscape.
dir	direction of edges, i.e., "none", "forward", "back", "both". This will be useful if the diagram is viewed by Ineato.

### Details

Note that a single PostScript (PDF) file can be obtained by dot, fdp, or neato.

```
dot -Tps <dot file> -o <ps file>
```

or

```
fdp -Tps <dot file> -o <ps file>
```

or

```
neato -Tps <dot file> -o <ps file>
```

See relevant documentations for other formats.

To preserve the original order of pedigree(s) in the data, you can examine the examples at the end of this document.

Under Cygwin/Linux/Unix, the PostScript file can be converted to Portable Document Format (PDF) default to Acrobat.

```
ps2pdf <ps file>
```

Use ps2pdf12, ps2pdf13, or ps2pdf14 for appropriate versions of Acrobat according to information given on the headline of <ps file>.

Under Linux, you can also visualize the .dot file directly via command,

```
dotty <dot file> &
```

We can extract the code below (or within pedtodot.Rd) to pedtodot and then use command:

```
sh pedtodot <pedigree file>
```

**Value**

For each pedigree, the function generates a .dot file to be used by dot. The collection of all pedigrees (\*.dot) can also be put together.

**Note**

This is based on the gawk script program pedtodot by David Duffy with minor changes.

**Author(s)**

David Duffy, Jing Hua Zhao

pedtodot(pre,dir="forward")

## End(Not run)

```

---

pedtodot\_verbatim      *Pedigree-drawing with graphviz*

---

### Description

Read a GAS or LINKAGE format pedigree, return a digraph in the dot language and optionally call dot/neato to make pedigree drawing.

### Usage

```
pedtodot_verbatim(f, run = FALSE, toDOT = FALSE, ...)
```

### Arguments

f	A data.frame containing pedigrees, each with pedigree id, individual id, father id, mother id, sex and affection status.
run	A flag to run dot/neato on the generated .dot file(s).
toDOT	A flag to generate script for DOT::dot().
...	Other flag(s) for DOT::dot().

### Details

This is a verbatim translation of the original pedtodot implemented in Bash/awk in contrast to ‘pedtodot’ which was largely a mirror. To check independently, try ‘xsel -i <<(cat pedtodot\_verbatim.R)’ or ‘cat pedtodot\_verbatim.R | xsel -i’ and paste into an R session.

### Value

No value is returned but outputs in .dot, .pdf, and .svg.

**Note**

Adapted from Bash/awk script by David Duffy

**Examples**

```
## Not run:
# pedigree p3 in pedtodot
pedtodot_verbatim(p3,run=TRUE,toDOT=TRUE,return="verbatim")

## End(Not run)
```

---

pfc

*Probability of familial clustering of disease*

---

**Description**

To calculate exact probability of familial clustering of disease

**Usage**

```
pfc(famdata, enum = 0)
```

**Arguments**

famdata	collective information of sib size, number of affected sibs and their frequencies.
enum	a switch taking value 1 if all possible tables are to be enumerated.

**Value**

The returned value is a list containing (tailp,sump,nenum are only available if enum=1:

**p** the probability of familial clustering

**stat** the deviances, chi-squares based on binomial and hypergeometric distributions, the degrees of freedom should take into account the number of marginals used

**tailp** the exact statistical significance

**sump** sum of the probabilities used for error checking

**nenum** the total number of tables enumerated

**Note**

pfc.sim

*Probability of familial clustering of disease*

---

**Description**

To calculate probability of familial clustering of disease using Monte Carlo simulation.

**Usage**

```
pfc.sim(famdata, n.sim = 1e+06, n.loop = 1)
```

**Arguments**

famdata	collective information of sib size, number of affected sibs and their frequencies.
n.sim	number of simulations in a single Monte Carlo run.
n.loop	total number of Monte Carlo runs.

**Value**

The returned value is a list containing:

**n.sim** a copy of the number of simulations in a single Monte Carlo run.

**n.loop** the total number of Monte Carlo runs.

**p** the observed p value.

**tailpl** accumulated probabilities at the lower tails.

**tailpu** simulated p values.

pgc

---

*Preparing weight for GENECOUNTING*

---

### Description

This function is a R port of the GENECOUNTING/PREPARE program which takes an array of genotyp data and collapses individuals with the same multilocus genotype. This function can also be used to prepare for the genotype table in testing Hardy-Weinberg equilibrium.

### Usage

```
pgc(data, handle.miss = 1, is.genotype = 0, with.id = 0)
```

### Arguments

data	the multilocus genotype data for a set of individuals.
handle.miss	a flag to indicate if missing data is kept, 0 = no, 1 = yes.
is.genotype	a flag to indicate if the data is already in the form of genotype identifiers.
with.id	a flag to indicate if the unique multilocus genotype identifier is generated.

**Value**

The returned value is a list containing:

**cdata** the collapsed genotype data

**wt** the frequency weight

**obscom** the observed number of combinations or genotypes

**idsave** optional, available only if with.id = 1

**Note**

Built on pgc.c.

**Author(s)**

Jing Hua Zhao

```

---

plot.hap.score	<i>Plot haplotype frequencies versus haplotype score statistics</i>
----------------	---

---

### Description

Method function to plot a class of type hap.score

### Usage

```
## S3 method for class 'hap.score'  
plot(x, ...)
```

### Arguments

x	The object returned from hap.score (which has class hap.score).
...	Optional arguments.

### Value

Nothing is returned.

This is a plot method function used to plot haplotype frequencies on the x-axis and haplotype-specific scores on the y-axis. Because hap.score is a class, the generic plot function can be used, which in turn calls this plot.hap.score function.

### References

Schaid DJ, Rowland CM, Tines DE, Jacobson RM, Poland GA (2002) Score tests for association of traits with haplotypes when linkage phase is ambiguous. *Amer J Hum Genet* 70:425-34

### See Also

# Example illustrating specific method plot function:  
plot.hap.score(save)  
  
## End(Not run)
```

---

print.hap.score	<i>Print a hap.score object</i>
-----------------	---------------------------------

---

### Description

Method function to print a class of type hap.score

### Usage

```
## S3 method for class 'hap.score'  
print(x, ...)
```

### Arguments

x	The object returned from hap.score (which has class hap.score).
...	Optional arguments.

### Value

Nothing is returned.

This is a print method function used to print information from hap.score class, with haplotype-specific information given in a table. Because hap.score is a class, the generic print function can be used, which in turn calls this print.hap.score function.

### References

Schaid DJ, Rowland CM, Tines DE, Jacobson RM, Poland GA (2002) Score tests for association of traits with haplotypes when linkage phase is ambiguous. *Amer J Hum Genet* 70:425-34

---

pvalue	<i>P value for a normal deviate</i>
--------	-------------------------------------

---

**Description**

P value for a normal deviate

**Usage**

```
pvalue(z, decimals = 2)
```

**Arguments**

z	normal deviate.
decimals	number of decimal places.

**Value**

P value as a string variable.

**Examples**

```
pvalue(-1.96)
```

---

qqfun	<i>Quantile-comparison plots</i>
-------	----------------------------------

---

**Description**

Plots empirical quantiles of a variable against theoretical quantiles of a comparison distribution.

**Usage**

```
qqfun(  
  x,  
  distribution = "norm",  
  ylab = deparse(substitute(x)),  
  xlab = paste(distribution, "quantiles"),  
  main = NULL,  
  las = par("las"),  
  envelope = 0.95,  
  labels = FALSE,  
  col = palette()[4],  
  lcol = palette()[2],  
  xlim = NULL,  
  ylim = NULL,  
)
```

```

    lwd = 1,
    pch = 1,
    bg = palette()[4],
    cex = 0.4,
    line = c("quartiles", "robust", "none"),
    ...
)

```

### Arguments

x	vector of numeric values.
distribution	root name of comparison distribution – e.g., norm for the normal distribution; t for the t-distribution.
ylab	label for vertical (empirical quantiles) axis.
xlab	label for horizontal (comparison quantiles) axis.
main	label for plot.
las	if 0, ticks labels are drawn parallel to the axis; set to 1 for horizontal labels (see <a href="#">par</a> ).
envelope	confidence level for point-wise confidence envelope, or FALSE for no envelope.
labels	vector of point labels for interactive point identification, or FALSE for no labels.
col	color for points; the default is the <i>fourth</i> entry in the current color palette (see <a href="#">palette</a> and <a href="#">par</a> ).
lcol	color for lines; the default is the <i>second</i> entry as above.
xlim	the x limits (x1, x2) of the plot. Note that $x1 > x2$ is allowed and leads to a reversed axis.
ylim	the y limits of the plot.
lwd	line width; default is 1 (see <a href="#">par</a> ). Confidence envelopes are drawn at half this line width.
pch	plotting character for points; default is 1 (a circle, see <a href="#">par</a> ).
bg	background color of points.
cex	factor for expanding the size of plotted symbols; the default is .4.
line	"quartiles" to pass a line through the quartile-pairs, or "robust" for a robust-regression line; the latter uses the <code>r1m</code> function in the MASS package. Specifying <code>line = "none"</code> suppresses the line.
...	arguments such as <code>df</code> to be passed to the appropriate quantile function.

### Details

Draws theoretical quantile-comparison plots for variables and for studentized residuals from a linear model. A comparison line is drawn on the plot either through the quartiles of the two distributions, or by robust regression.

Any distribution for which quantile and density functions exist in R (with prefixes `q` and `d`, respectively) may be used. Studentized residuals are plotted against the appropriate t-distribution.

This is adapted from `qq.plot` of package `car` with different values for points and lines, more options, more transparent code and examples in the current setting. Another similar but sophisticated function is `qqmath` of package `lattice`.

**Value**

NULL. These functions are used only for their side effect (to make a graph).

**Author(s)**

John Fox, Jing Hua Zhao

## End(Not run)
```

---

qqunif

*Q-Q plot for uniformly distributed random variable*

---

**Description**

This function produces Q-Q plot for a random variable following uniform distribution with or without using log-scale. Note that the log-scale is by default for type "exp", which is a plot based on exponential order statistics. This appears to be more appropriate than the commonly used procedure whereby the expected value of uniform order statistics is directly log-transformed.

**Usage**

```
qqunif(  
  u,  
  type = "unif",  
  logscale = TRUE,  
  base = 10,  
  col = palette()[4],  
  lcol = palette()[2],  
  ci = FALSE,  
  alpha = 0.05,  
  ...  
)
```

**Arguments**

<code>u</code>	a vector of uniformly distributed random variables.
<code>type</code>	string option to specify distribution: "unif"=uniform, "exp"=exponential.
<code>logscale</code>	to use logscale.
<code>base</code>	the base of the log function.
<code>col</code>	color for points.
<code>lcol</code>	color for the diagonal line.
<code>ci</code>	logical option to show confidence interval.
<code>alpha</code>	1-confidence level, e.g., 0.05.
<code>...</code>	other options as appropriate for the qqplot function.

**Value**

The returned value is a list with components of a qqplot:

`x` expected value for uniform order statistics or its  $-\log(\text{base})$  counterpart  
`y` observed value or its  $-\log(\text{base})$  counterpart

qtl2dplot

*2D QTL plot*

---

**Description**

This function is both used as its own for a 2d plot and/or generate data for a plotly counterpart.

**Usage**

```
qtl2dplot(
  d,
  chrLen = gap::hg19,
  snp_name = "SNP",
  snp_chr = "Chr",
  snp_pos = "bp",
  gene_chr = "p.chr",
  gene_start = "p.start",
  gene_end = "p.end",
  trait = "p.target.short",
  gene = "p.gene",
  TSS = FALSE,
  cis = "cis",
  value = "log10p",
  plot = TRUE,
  cex.labels = 0.6,
  cex.points = 0.6,
  xlab = "QTL position",
  ylab = "Gene position"
)
```

**Arguments**

**d** Data to be used.

**chrLen** lengths of chromosomes for specific build: hg18, hg19, hg38.

snp_name	variant name.
snp_chr	variant chromosome.
snp_pos	variant position.
gene_chr	gene chromosome.
gene_start	gene start position.
gene_end	gene end position.
trait	trait name.
gene	gene name.
TSS	to use TSS when TRUE.
cis	cis variant when TRUE.
value	A specific value to show.
plot	to plot when TRUE.
cex.labels	Axis label extension factor.
cex.points	Data point extension factor.
xlab	X-axis title.
ylab	Y-axis title.

**Value**

positional information.

**Examples**

```
## Not run:
INF <- Sys.getenv("INF")
d <- read.csv(file.path(INF,"work","INF1.merge.cis.vs.trans"),as.is=TRUE)
r <- qt12dplot(d)

```

---

qt12dplotly

*2D QTL plotly*

---

**Description**

2D QTL plotly

**Usage**

```

qtl2dplotly(
  d,
  chrLen = gap::hg19,
  qtl.id = "SNPid:",
  qtl.prefix = "QTL:",
  qtl.gene = "Gene:",
  target.type = "Protein",
  TSS = FALSE,
  xlab = "QTL position",
  ylab = "Gene position",
  ...
)

```

**Arguments**

d	Data in qtl2dplot() format.
chrLen	Lengths of chromosomes for specific build: hg18, hg19, hg38.
qtl.id	QTL id.
qtl.prefix	QTL prefix.
qtl.gene	QTL gene.
target.type	Type of target, e.g., protein.
TSS	to use TSS when TRUE.
xlab	X-axis title.
ylab	Y-axis title.
...	Additional arguments, e.g., target, log10p, to qtl2dplot.

**Value**

A plotly figure.

**Examples**

```

## Not run:
INF <- Sys.getenv("INF")
d <- read.csv(file.path(INF, "work", "INF1.merge.cis.vs.trans"), as.is=TRUE)
r <- qtl2dplotly(d)
htmlwidgets::saveWidget(r, file=file.path(INF, "INF1.qtl2dplotly.html"))
r

## End(Not run)

```

---

`qtl3dplotly`*3D QTL plot*

---

**Description**

3D QTL plot

**Usage**

```
qtl3dplotly(  
  d,  
  chrLen = gap::hg19,  
  zmax = 300,  
  qtl.id = "SNPid:",  
  qtl.prefix = "QTL:",  
  qtl.gene = "Gene:",  
  target.type = "Protein",  
  TSS = FALSE,  
  xlab = "QTL position",  
  ylab = "Gene position",  
  ...  
)
```

**Arguments**

<code>d</code>	Data in <code>qtl2d()</code> format.
<code>chrLen</code>	Lengths of chromosomes for specific build: hg18, hg19, hg38.
<code>zmax</code>	Maximum value (e.g., $-\log_{10}p$ ) to truncate, above which they would be set to this value.
<code>qtl.id</code>	QTL id.
<code>qtl.prefix</code>	QTL prefix.
<code>qtl.gene</code>	QTL target gene.
<code>target.type</code>	Type of target, e.g., protein.
<code>TSS</code>	to use TSS when TRUE.
<code>xlab</code>	X-axis title.
<code>ylab</code>	Y-axis title.
<code>...</code>	Additional arguments, e.g., to <code>qtl2dplot()</code> .

**Value**

A plotly figure.

**Examples**

```
## Not run:
suppressMessages(library(dplyr))
INF <- Sys.getenv("INF")
d <- read.csv(file.path(INF, "work", "INF1.merge.cis.vs.trans"), as.is=TRUE) %>%

## End(Not run)
```

---

qtlClassifier

*A QTL cis/trans classifier*

---

**Description**

The function obtains QTL (simply called SNP here) cis/trans classification based on gene positions.

**Usage**

```
qtlClassifier(geneSNP, SNPPos, genePos, radius)
```

**Arguments**

geneSNP	data.frame with columns on gene, SNP and biomarker (e.g., expression, protein).
SNPPos	data.frame containing SNP, chromosome and position.
genePos	data.frame containing gene, chromosome, start and end positions.
radius	flanking distance.

**Value**

It returns a geneSNP-prefixed data.frame with the following columns,

**geneChrom** gene chromosome  
**geneStart** gene start  
**geneEnd** gene end  
**SNPChrom** pQTL chromosome  
**SNPPos** pQTL position  
**Type** cis/trans labels

**Note**

This is adapted from iBMQ/eqtClassifier as an xQTL (x=e, p, me, ...) classifier.

**See Also**[cis.vs.trans.classification](#)**Examples**

```
## Not run:
merged <- read.delim("INF1.merge",as.is=TRUE)

options(width=200)
geneSNP <- merge(hits[c("prot","SNP","log10p")],
                inf1[c("prot","gene")],by="prot")[c("gene","SNP","prot","log10p")]
SNPPos <- hits[c("SNP","Chr","bp")]
genePos <- inf1[c("gene","chr","start","end")]
cvt <- qtlClassifier(geneSNP,SNPPos,genePos,1e6)
cvt
cistrans <- cis.vs.trans.classification(hits,inf1,"uniprot")
cis.vs.trans <- with(cistrans,data)
cistrans.check <- merge(cvt[c("gene","SNP","Type")],cis.vs.trans[c("p.gene","SNP","cis.trans")],
                      by.x=c("gene","SNP"),by.y=c("p.gene","SNP"))
with(cistrans.check,table(Type,cis.trans))

## End(Not run)
```

read.ms.output

*A utility function to read ms output***Description**

This function reads in the output of the program ms, a program to generate samples under a variety of neutral models.

**Usage**

```
read.ms.output(
  msout,
  is.file = TRUE,
  xpose = TRUE,
  verbose = TRUE,
  outfile = NULL,
  outfileonly = FALSE
)
```

**Arguments**

<code>msout</code>	an ms output.
<code>is.file</code>	a flag indicating ms output as a system file or an R object.
<code>xpose</code>	a flag to obtain the tranposed format as it is (when TRUE).
<code>verbose</code>	when TRUE, display on screen every 1000 for large nsam.
<code>outfile</code>	to save the haplotypes in a tab-delimited ASCII file.
<code>outfileonly</code>	to reset gametes to NA when nsam/nreps is very large and is useful with outfile. The returned value is a list storing the results.
<b>call</b>	system call to ms
<b>seed</b>	random number seed to ms
<b>nsam</b>	number of copies of the locus in each sample
<b>nreps</b>	the number of independent samples to generate
<b>segsites</b>	a vector of the numbers of segregating sites
<b>times</b>	vectors of time to most recent ancestor (TMRCA) and total tree lengths
<b>positions</b>	positions of polymorphic sites on a scale of (0,1)
<b>gametes</b>	a list of haplotype arrays
<b>probs</b>	the probability of the specified number of segregating sites given the genealogical history of the sample and the value to -t option

**Details**

The argument indicates either a file name or a vector of character strings, one string for each line of the output of ms. As with the second case, it is appropriate with `system(,intern=TRUE)`, see example below.

**Author(s)**

D Davison, RR Hudson, JH Zhao

**References**

**Examples**

```
## Not run:
# Assuming ms is on the path

system("ms 5 4 -s 5 > ms.out")
msout1 <- read.ms.output("ms.out")

system("ms 50 4 -s 5 > ms.out")
msout2 <- read.ms.output("ms.out",outfile="out",outfileonly=TRUE)
```

```
msout <- system("ms 5 4 -s 5 -L", intern=TRUE)
msout3 <- read.ms.output(msout,FALSE)

## End(Not run)
```

---

ReadGRM *A function to read GRM file*

---

**Description**

A function to read GRM file

**Usage**

```
ReadGRM(prefix = 51)
```

**Arguments**

prefix            file root.

---

ReadGRMBin *A function to read GRM binary files*

---

**Description**

A function to read GRM binary files

**Usage**

```
ReadGRMBin(prefix, AllN = FALSE, size = 4)
```

**Arguments**

prefix            file root.  
AllN              a logical variable.  
size               size.

**Details**

Modified from GCTA documentation

revStrand *Allele on the reverse strand*

---

**Description**

The function obtains allele on the reverse strand.

**Usage**

```
revStrand(allele)
```

**Arguments**

allele            Allele to reverse.

**Value**

Allele on the reverse strand.

**Examples**

```
## Not run:
alleles <- c("a", "c", "G", "t")
reverse_strand(alleles)

## End(Not run)
```

---

runshinygap *Start shinygap*

---

**Description**

This function starts the interactive 'shinygap' shiny web application that allows for flexible model specification.

**Usage**

```
runshinygap(...)
```

**Arguments**

...            Additional arguments passed to the 'runApp' function from the 'shiny' package.

**Details**

The 'shiny' based web application allows for flexible model specification for the implemented study designs.

**Value**

These are design specific.

---

s2k

*Statistics for 2 by K table*

---

**Description**

This function calculates one-to-others and maximum accumulated chi-squared statistics for a 2 by K contingency table.

**Usage**

```
s2k(y1, y2)
```

**Arguments**

**y1** a vector containing the first row of a 2 by K contingency table.  
**y2** a vector containing the second row of a 2 by K contingency table.

**Value**

The returned value is a list containing:

**x2a** the one-to-other chisquare.  
**x2b** the maximum accumulated chisquare.  
**col1** the column index for x2a.  
**col2** the column index for x2b.  
**p** the corresponding p value.

**Note**

The lengths of y1 and y2 should be the same.

y2 <- c(0, 6,31,49,120,27,15,8,14,25, 3, 9,3)

result <- s2k(y1,y2)

## End(Not run)
```

---

sentinels

*Sentinel identification from GWAS summary statistics*

---

**Description**

This function accepts an object containing GWAS summary statistics for signal identification as defined by flanking regions. As the associate P value could be extremely small, the effect size and its standard error are used.

**Usage**

```
sentinels(
  p,
  pid,
  st,
  debug = FALSE,
  flanking = 1e+06,
  chr = "Chrom",
  pos = "End",
  b = "Effect",
  se = "StdErr",
  log_p = NULL,
  snp = "MarkerName",
  sep = ", "
)
```

**Arguments**

p	an object containing GWAS summary statistics.
pid	a phenotype (e.g., protein) name in pGWAS.
st	row number as in p.
debug	a flag to show the actual data.
flanking	the width of flanking region.
chr	Chromosome name.
pos	Position.

b	Effect size.
se	Standard error.
log_p	log(P).
snp	Marker name.
sep	field delimiter.

## Details

A distance-based approach was consequently used and reframed as an algorithm here. It takes as input signals multiple correlated variants in particular region(s) which reach genomewide significance and output three types of sentinels in a region-based manner. For a given protein and a chromosome, the algorithm proceeds as follows:

### Algorithm sentinels

Step 1. for a particular collection of genomewide significant variants on a chromosome, the width of the region is calculated according to the start and end chromosomal positions and if it is smaller than the flanking distance, the variant with the smallest P value is taken as sentinel (I) otherwise goes to step 2.

Step 2. The variant at step 1 is only a candidate and a flanking region is generated. If such a region contains no variant the candidate is recorded as sentinel (II) and a new iteration starts from the variant next to the flanking region.

Step 3. When the flanking is possible at step 2 but the P value is still larger than the candidate at step 2, the candidate is again recorded as sentinel (III) but next iteration starts from the variant just after the variant at the end position; otherwise the variant is updated as a new candidate where the next iteration starts.

Note Type I signals are often seen from variants in strong LD at a cis region, type II results seen when a chromosome contains two trans signals, type III results seen if there are multiple trans signals.

Typically, input to the function are variants reaching certain level of significance and the function identifies minimum p value at the flanking interval; in the case of another variant in the flanking window has smaller p value it will be used instead.

For now key variables in p are "MarkerName", "End", "Effect", "StdErr", "P.value", where "End" is as in a bed file indicating marker position, and the function is set up such that row names are numbered as 1:nrow(p); see example below. When log\_p is specified, log(P) is used instead, which is appropriate with output from METAL with LOGPVALUE ON. In this case, the column named log(P) in the output is actually log<sub>10</sub>(P).

## Value

The function give screen output.

## Examples

```
## Not run:  
## OPG as a positive control in our pGWAS  
require(gap.datasets)  
data(OPG)
```

```

p <- reshape::rename(OPGtbl, c(Chromosome="Chrom", Position="End"))
chrs <- with(p, unique(Chrom))
for(chr in chrs)
{
  ps <- subset(p[c("Chrom", "End", "MarkerName", "Effect", "StdErr")], Chrom==chr)
  row.names(ps) <- 1:nrow(ps)
  sentinels(ps, "OPG", 1)
}
subset(OPGrsid, MarkerName=="chr8:120081031_C_T")
subset(OPGrsid, MarkerName=="chr17:26694861_A_G")
## log(P)
p <- within(p, {logp <- log(P.value)})
for(chr in chrs)
{
  ps <- subset(p[c("Chrom", "End", "MarkerName", "logp")], Chrom==chr)
  row.names(ps) <- 1:nrow(ps)
  sentinels(ps, "OPG", 1, log_p="logp")
}
## to obtain variance explained
tbl <- within(OPGtbl, chi2n <- (Effect/StdErr)^2/N)
s <- with(tbl, aggregate(chi2n, list(prot), sum))
names(s) <- c("prot", "h2")
sd <- with(tbl, aggregate(chi2n, list(prot), sd))
names(sd) <- c("p1", "sd")
m <- with(tbl, aggregate(chi2n, list(prot), length))
names(m) <- c("p2", "m")
h2 <- cbind(s, sd, m)
ord <- with(h2, order(h2))
sink("h2.dat")
print(h2[ord, c("prot", "h2", "sd", "m")], row.names=FALSE)
sink()
png("h2.png", res=300, units="in", width=12, height=8)
np <- nrow(h2)
with(h2[ord,], {
  plot(h2, cex=0.4, pch=16, xaxt="n", xlab="protein", ylab=expression(h^2))
  xtick <- seq(1, np, by=1)
  axis(side=1, at=xtick, labels = FALSE)
  text(x=xtick, par("usr")[3], labels = prot, srt = 75, pos = 1, xpd = TRUE, cex=0.5)
})
dev.off()
write.csv(tbl, file="INF1.csv", quote=FALSE, row.names=FALSE)

## End(Not run)

```

**Description**

Eventually, this will be a set of functions specifically for single nucleotide polymorphisms (SNPs), which are biallelic markers. This is particularly relevant to the genomewide association studies (GWAS) using GeneChips and in line with the classic generalised single-locus model. snp.HWE is from Abecasis's website and yet to be adapted for chromosome X.

**Usage**

```
snp.ES(beta, SE, N)
```

```
snp.HWE(g)
```

```
PARn(p, RRlist)
```

```
snp.PAR(RR, MAF, unit = 2)
```

**Arguments**

beta	Regression coefficient.
SE	Standard error for beta.
N	Sample size.
g	Observed genotype vector.
p	genotype frequencies.
RRlist	A list of RRs.
RR	Relative risk.
MAF	Minor allele frequency.
unit	Unit to exponentiate for homozygote.

**Details**

snp.ES provides effect size estimates based on the linear regression coefficient and standard error. For logistic regression, we can have similar idea for  $\log(\text{OR})$  and  $\log(\text{SE}(\text{OR}))$ .

snp.HWE gives an exact Hardy-Weinberg Equilibrium (HWE) test and it return -1 in the case of misspecification of genotype counts.

snp.PAR calculates the the population attributable risk (PAR) for a particular SNP. Internally, it calls for an internal function PARn, given a set of frequencies and associate relative risks (RR). Other 2x2 table statistics familiar to epidemiologists can be added when necessary.

---

`snptest_sample`*A utility to generate SNPTEST sample file*

---

**Description**

A utility to generate SNPTEST sample file

**Usage**

```
snptest_sample(  
  data,  
  sample_file = "snptest.sample",  
  ID_1 = "ID_1",  
  ID_2 = "ID_2",  
  missing = "missing",  
  C = NULL,  
  D = NULL,  
  P = NULL  
)
```

**Arguments**

<code>data</code>	Data to be used.
<code>sample_file</code>	Output filename.
<code>ID_1</code>	ID_1 as in the sample file.
<code>ID_2</code>	ID_2 as in the sample file.
<code>missing</code>	Missing data column.
<code>C</code>	Continuous variables.
<code>D</code>	Discrete variables.
<code>P</code>	Phenotypic variables.

**Value**

Output file in SNPTEST's sample format.

**Examples**

```
## Not run:  
d <- data.frame(ID_1=1, ID_2=1, missing=0, PC1=1, PC2=2, D1=1, P1=10)  
snptest_sample(d, C=paste0("PC", 1:2), D=paste0("D", 1:1), P=paste0("P", 1:1))  
  
## End(Not run)
```

tsc

*Power calculation for two-stage case-control design***Description**

This function gives power estimates for two-stage case-control design for genetic association.

**Usage**

```
tsc(model, GRR, p1, n1, n2, M, alpha.genome, pi.samples, pi.markers, K)
```

**Arguments**

model	any in c("multiplicative","additive","dominant","recessive").
GRR	genotype relative risk.
p1	the estimated risk allele frequency in cases.
n1	total number of cases.
n2	total number of controls.
M	total number of markers.
alpha.genome	false positive rate at genome level.
pi.samples	sample% to be genotyped at stage 1.
pi.markers	markers% to be selected (also used as the false positive rate at stage 1).
K	the population prevalence.

**Details**

The false positive rates are calculated as follows,

$$P(|z_1| > C_1)P(|z_2| > C_2, \text{sign}(z_1) = \text{sign}(z_2))$$

and

$$P(|z_1| > C_1)P(|z_j| > C_j | |z_1| > C_1)$$

for replication-based and joint analyses, respectively; where  $C_1$ ,  $C_2$ , and  $C_j$  are thresholds at stages 1, 2 replication and joint analysis,

$$z_1 = z(p_1, p_2, n_1, n_2, \text{pi.samples})$$

$$z_2 = z(p_1, p_2, n_1, n_2, 1 - \text{pi.samples})$$

$$z_j = \text{sqrt}(\text{pi.samples}) * z_1 + \text{sqrt}(1 - \text{pi.samples}) * z_2$$

**Value**

The returned value is a list containing a copy of the input plus output as follows,

**model** any in c("multiplicative","additive","dominant","recessive").

**GRR** genotype relative risk.

**p1** the estimated risk allele frequency in cases.

**pprime** expected risk allele frequency in cases.

**p** expected risk allele frequency in controls.

**n1** total number of cases.

**n2** total number of controls.

**M** total number of markers.

**alpha.genome** false positive rate at genome level.

**pi.samples** sample% to be genotyped at stage 1.

**pi.markers** markers% to be selected (also used as the false positive rate at stage 1).

**K** the population prevalence.

**C** thresholds for no stage, stage 1, stage 2, joint analysis.

**power** power corresponding to C.

**Note**

solve.skol is adapted from CaTS.

## End(Not run)

```

---

whscore

*Whittemore-Halpern scores for allele-sharing*

---

### Description

Allele sharing score statistics.

### Usage

```
whscore(allele, type)
```

### Arguments

allele	a matrix of alleles of affected pedigree members.
type	0 = pairs, 1 = all.

### Value

The returned value is the value of score statistic.

### Note

adapted from GENEHUNTER.

WriteGRM

*A function to write GRM file*

---

**Description**

A function to write GRM file

**Usage**

```
WriteGRM(prefix = 51, id, N, GRM)
```

**Arguments**

prefix	file root.
id	id.
N	sample size.
GRM	a GRM.

---

WriteGRMBin	<i>A function to write GRM binary file</i>
-------------	--

---

**Description**

A function to write GRM binary file

**Usage**

```
WriteGRMBin(prefix, grm, N, id, size = 4)
```

**Arguments**

prefix	file root.
grm	a GRM.
N	Sample size.
id	id.
size	size.

---

xy	<i>Conversion of chromosome names to strings</i>
----	--

---

**Description**

This function converts x=1:24 to 1:22, X, Y

**Usage**

```
xy(x)
```

**Arguments**

x	(alpha)numeric value indicating chromosome.
---	---

**Value**

As indicated.
